Dr. Alexander Miller has succeeded Dr. Heron Watson, who retires, as Lecturer on Surgery in the Royal College of Surgeons; and Dr. MacGillivray takes Professor Chiene's place at Minto House. Dr. P. Young gives a qualifying course of lectures on Midwifery and Diseases of Women at Park Place, and Dr. Berry Hart is to deliver a course of lectures on Diseases of Women in the same lecture-room.

Dr. Miller gave his introductory lecture on Tuesday to a large audience of practitioners and students. The subject which he selected, "Four and a half years' experience in the lock wards of the Royal Infirmary," was treated in a masterly manner, and was, in short, a summary of the lecturer's personal experience in the treatment of venereal affections. Dr. Miller promises, like his father (the late Professor of Surgery in the University), to be a successful teacher.

Dr. Claud Muirhead has been appointed successor to Dr. William Robertson, as Medical Referee to the Scottish Widows' Fund. This is a most valuable appointment, and is much coveted by the profession here.

Dr. Blair Cunynghame has, I understand, been appointed Superintendent of the Statistical Department in the Registrar-General's Office, Edinburgh—another valuable appointment which was held by the late Dr. Robertson.

#### GLASGOW.

(From our own Correspondent.)

WITH regard to the chloroform question, and the rules which the managers of the Royal Infirmary proposed to lay down for the guidance of the surgeons in the administration of anaesthetics, the whole matter is now, as it should have been at first, referred to the medical committee. This removes part of the very natural objection of the surgical staff to receive instructions from a lay body, in reference to a matter purely surgical. The Faculty of Physicians and Surgeons also have departed from their intention of discussing the question. In the meantime, the public of Glasgow ought surely to be well informed in subjects physiological. During the course of this winter we are to have another course of health lectures, under the auspices of our local Young Men's Christian Association. Professor G. Buchanan delivered the first of these last week, on the structure of the body, to a somewhat select audience. The second was delivered on Tuesday, by Dr. W. J. Fleming, on digestion. In the remainder of the course are included lectures on the eye, the ear, the teeth, the skin, and the hygiene of infancy; the last of the course being, with what many regard as questionable taste, on "healthy motherhood," to ladies only. This is probably the complement of the very popular lecture delivered last year by another rising obstetrician, on "healthy womanhood." Some rather silly hostility has been manifested in certain quarters to these health lectures, on the ground mainly that they afford opportunity to ambitious men to pass before the public as learned specialists, to the detriment of their professional brethren. It is, however, surely not wrong that

the public should have such subjects as those named above put before them in a simple and popular way; and by whom could such instruction be more appropriately given than by medical men?

Some months ago a writer in the *Sanitary Journal* was at considerable pains to show that various of our coast health-resorts, especially on the Firth of Clyde, were the reverse of healthy resorts; that in fact, so far as their meagre health statistics indicated anything, they proved that these places had a very exceptionally high death-rate. Amongst these towns Gourock was placed highest, with a death-rate of 36.4 per 1000. In reference to this locality, the authorities stated at the time that the majority of the deaths noted occurred in an institution, the Smithston Asylum, which, though technically in their registration district, did not really belong to them, but to Greenock. During the last few months the Gourock Police Commissioners have kept accurate mortality statistics of the borough proper, and have just published them. From them we learn that during July, August, and September, when the town is usually crowded with visitors, there occurred 33 deaths in the registration district; 15 of these took place in the Smithston Asylum, which is outside of the burgh boundary, while another was also in the registration district, but outside the same boundary, so that the actual number of deaths in Gourock proper was 17. Calculating on the last census returns, this gives a death-rate of 10 per 1000 of the population. It is right that these facts should be known, as Gourock is a much frequented watering-place.

Out of 115 students who went up recently for the first professional examination at Glasgow University, no fewer than 54 were "plucked." This is a very high percentage of rejections, and points either to great stringency of examination, or to a falling off in the quality of the men presenting themselves. The subjects included in this examination are elementary anatomy, chemistry, and botany.

#### SCOTTISH NOTES.

(From our own Correspondent.)

THE proper teaching of pathology at Aberdeen is not likely to be facilitated if action is taken on the lines suggested by the Infirmary Committee at their meeting last week. Compromise may in many cases be necessary, but this seems emphatically a case where firmness was demanded. The committee will recommend to the general court of directors, meeting in December, that their present pathologist shall take the duties alternately with the newly-appointed professor. Had this been an amicable arrangement between Dr. Rodger and Professor Hamilton, discomfort might possibly have been avoided, but notoriously this is not the case; and it is hoped that by December a clearer course may be open. Dr. Rodger deserves every consideration from the directors; he has signified no wish for assistance in the performance of his duties, and has offered to the professor the free use of what material the infirmary may afford, as well as full advantage of the museum he has done so much to render valuable. If it be true, as is asserted, that Dr. Hamilton made formal application to the directors to be appointed pathologist, well knowing that there was no vacancy in that office, and that he is not willing to accept Dr. Rodger's offer, which met the views of the Museum Committee, there seems no proper course but to refuse Dr. Hamilton's application, and that on the simple ground that there is no vacancy.

Your strictures upon the Edinburgh Colleges regarding the manner of election to the Fellowship, excite much attention in the north, and, though the profession feel a just pride in the history of those ancient bodies, there can be no doubt that the evil you refer to has been noticed for some time past, and deeply deplored. The many eminent Fellows of the College of Surgeons must feel that pecuniary consideration should not alone guide their council, and the increasing number of young and totally undistinguished names added to their list has already reduced the value of what ought to be a high honour to a position which a loyal Scotchman will not wish to characterise. As the Fellowship no longer confers such distinction in the profession as is attributed to it by the public, it becomes a hardship that its possession

should be still a *sine qua non* to men who wish infirmiry appointments or recognition as lecturers at the various schools. The same remarks apply, at least, equally to the Glasgow Faculty, and, in both instances, their splendid libraries are now the chief attractions. While much has been done towards steadily raising the requirements of licentiates, it is unfortunate that the Fellowships should no longer be a guarantee of superior merit.

Prosecution for professional accounts is so unusual that the public, knowing the reluctance of medical men to appear in court, too often profit by this unwillingness, and defraud the profession of very large sums. A certain unpopularity attaches to those who in this way claim their own, and, as a consequence, isolated action is not frequently taken. It might be well if the example of Dr. Collins, late of Bervie, was followed, and able, but unwilling, debtors were made to settle their accounts. A few days ago, Dr. Collins, at the Stonehaven sheriff court, sued thirty-eight of his late patients for sums due; few, if any, of these put in an appearance, and decree was given in all the cases. Such wholesome and wholesale action will not be lost upon the district.

Dr. Andrew Wilson, of Edinburgh, has now commenced a series of lectures under the Combe Trust in various towns throughout Scotland. A general view of physiology will be presented in the eight lectures which make up the course, and special reference will be made to the value of a due observance of physiological laws if personal and public health is to be well maintained. The lecturer's past success ensures him a cordial reception everywhere, and his first two appearances in Perth indicate a hearty appreciation of physiological teaching on the part of those it is intended to reach. If all is true that is written regarding the sanitary condition and polluted water supply of that city, an excellent field is open for Dr. Wilson. In the second lecture the value of vivisection was convincingly shown.

Typhoid fever has appeared in an epidemic form in the parish of Bonhill, Vale of Leven. The cases, so far, have mostly occurred in the village of Jamestown, where about thirty people are affected. Some fatality is already reported, and the type of the disease is said to be severe.

## IRELAND.

(From our own Correspondent.)

THE ceremony of conferring the degrees of the Royal University of Ireland is expected to take place on the 8th proximo. His Grace the Duke of Abercorn, Chancellor of the University, will preside.

At a special meeting of the Dublin Town Council, held last Monday, presentments amounting to £4595 were passed for the support of various hospitals. This sum included £300 to Mercer's, Jervis-street, Meath, Hospital for Incurables, Sir Patrick Dun's (with £50 for Maternity), Rotundo, Cork-street Fever, and City of Dublin Hospitals; £150 to St. Mark's Ophthalmic, Steevens', and Children's Hospitals; £520 to the Coombe Lying-in Hospital; £400 to St. Vincent's and Mater Misericordiae Hospitals; £100 to the National Orthopaedic Hospital and the National Eye and Ear Infirmary, and £25 to the Throat and Ear Hospital. A proposal to increase the salary of Dr. Whyte, coroner for the city, to £700 per annum was defeated.

The Academy of Medicine of Ireland, which is intended to absorb the Medical, Surgical, Pathological, and Obstetrical Societies, will, it is expected, begin its work in the present session. The scheme proposes that there shall be four sections, devoted respectively to medicine, surgery, obstetrics, and pathology; and the subscriptions proposed are two guineas for Fellows (of whom there will be 100), one guinea for Members, ten shillings for Associates, and five shillings for Student Associates. It is intended to issue an annual volume of Transactions, which will be supplied free to Fellows and Members.

It has recently been stated that the Belfast medical student, as a rule, does not receive any practical knowledge of the diseases of women and children, and of diseases of the eye and ear, in consequence of the Royal Hospital, the only general hospital in Belfast, not having had apartments for these diseases, or money or space to found such in an efficient manner without impairing the utility of the hospital.

Further, candidates for a degree in medicine of the Royal University of Ireland are required to produce a certificate "of having attended at a recognised midwifery hospital, where clinical instruction in midwifery and diseases of women and children is given for a period of six months, or of having attended for six months at a midwifery dispensary where similar clinical instruction is given." To remedy this defect it has been proposed that the special hospitals should be amalgamated with the Belfast Royal Hospital, but there are great difficulties in the way of accomplishing the object, more particularly as regards the arrangement of the hospital fees; for it naturally follows that if these special hospitals throw open their doors to students of the Royal Hospital, their medical officers will expect some remuneration from the students attending their classes, which probably the staff of the Belfast Royal Hospital may be disinclined to agree to. The only course would be for the latter to increase their hospital fees and thus recoup themselves, or let the medical students not only take out the practice of the general hospital, but also that of an ophthalmic hospital, and attend the maternity department of the Union Hospital.

The Londonderry City and County Infirmary is an institution which alleviates a large amount of suffering at a very moderate outlay. During last year 423 accidents were treated as external cases, including dislocations, fractures, burns, and wounds, and 768 patients were admitted to wards. Seventy-one operations were performed with only one death. The Hospital Sunday collections only amounted to £33. Collections in aid of the Dublin Hospital Sunday Fund will be held this year on the 12th November.

An address and testimonial have recently been presented to Dr. Thomas D. Foreman, Ballynahinch, previous to his departure from that place to settle in Denton, Manchester. The address was beautifully illuminated, and the presentation consisted of an elegant tea and coffee service with salver. Dr. Foreman, after the presentation had been made, entertained the deputation and a number of his neighbouring medical brethren at supper at Walker's Hotel.

## PARIS.

(From our Paris Correspondent.)

AT a clinical lecture at the Hôpital de la Pitié, Professor Lasègue made some very interesting remarks on the pathology and treatment of diabetes. He divides diabetic patients into two classes: fat and lean, according as they may be found in either of these conditions. He also divides them into small and great diabetics, according to the quantity of sugar which their urine may contain. The patient that excretes twenty grammes of sugar a day may be classed among the former; those who pass more than thirty or forty belong to the second class. Professor Lasègue attaches great importance to this division, for as the small diabetic patient never becomes a great one, each class retains its peculiar character; from which it may be concluded that a patient who presents great irregularities in the quantity of sugar he excretes, and appears to pass from one class to the other, is affected more with accidental or casual diabetes than with the true affection. A third class of diabetic patients is what Professor Lasègue calls "les diabétiques fixés," and these may be found among the two former classes. In this class of cases the quantity of sugar excreted varies only by a few grammes, whatsoever the treatment employed, or the diet adopted, but this should not be considered of much importance in a prognostic point of view, the quantity of sugar not being a fair criterion of the gravity of the disease; for although the proportion of sugar in the urine may remain stationary, the extent of the general disorder of the system may still be very considerable. This, however, does not apply to patients who pass 200 or 300 grammes of sugar in the twenty-four hours: these cases must be considered exceptional, and always of some gravity. M. Lasègue establishes two other forms of diabetes, which he designates the remittent and intermittent; in the first case the quantity of sugar is considerably reduced; in the second the sugar disappears, sometimes even completely, at certain periods; and although these states of remission or intermission may be considered more favourable than the other forms, yet patients of this category become cachectic,

as patients of the other classes almost invariably do. This state, according to M. Lasègue, would constitute the principal indication of treatment; but he does not approve of the severe restrictions generally placed upon the diet and regimen of diabetic patients. He allows them to continue their usual mode of living, not even depriving them of farinaceous substances, or the use in moderation of sugar, water, or wine. As for gluten bread, so much prescribed for these cases, M. Lasègue condemns it *in toto* as not only being worthless, but it ends by disgusting the patient, takes away his appetite, and so hastens the cachectic state, which it is the very object of the physician to avert by all the means in his power.

During the holidays of the Faculty of Medicine the professors avail themselves of a well-earned respite, being replaced at the hospitals by agrégés or sub-professors. At the Hôpital de la Charité, Dr. Landouzy, who acted for Professor Hardy, delivered a very interesting lecture on the contagiousness of tuberculosis. Dr. Landouzy is evidently in favour of the theory of the contagiousness of this affection, as will be seen from what follows, and in order to give some support to his belief he prefaced his observations by the remark that in many diseases contagiousness is admitted without its being positively proved. Having referred to the experiments of Villemin and others in favour of this doctrine, he cited a case which came under the observation of his father, and which he thinks could leave no doubt as to the contagiousness of tuberculosis. He referred to another case recorded by Dr. Weber in support of his theory, which he considers is sufficiently conclusive. The case observed by his father was that of a young physician, who, being affected with tuberculosis, but imagining himself cured, got married and had two children. Soon after the birth of his second child he had another access of pulmonary tuberculosis, when he was advised to spend his winters in a mild climate. He consequently went to Algiers, where he spent his first winter without much difficulty. The disease, however, continued to progress, and during the second year he became considerably worse, which induced him to return to France, his native clime, where he soon died. His wife, who was till then in robust health, soon followed her husband to the grave, with one of her sons, both of whom succumbed under the same malady. This case necessarily suggests the question, whether mother and child were not affected by contagion or transmission of the malady of the father. Dr. Landouzy replies, that although he would speak with reserve, yet it is the duty of every physician to act in such circumstances as if the contagiousness of tuberculosis had been proved. There is one point, however, in Dr. Landouzy's lecture which deserves particular notice—viz., the mortality among military men from tuberculosis. He states that in 1872, in France, the proportion of deaths from this malady was 452 per 1000; in England it was 782 per 1000; and he makes the startling remark, that the British army, during the rigorous winter of 1854-1855, before Sebastopol, lost fewer men from pulmonary phthisis than in their barracks. In this circumstance also Dr. Landouzy sees great presumption in favour of the contagiousness of the malady in question.

Dr. Gustave Le Bon lately submitted to the Academy of Sciences two new substances, the glyceroborate of calcium and the glyceroborate of sodium, which, according to him, possess powerful antiseptic properties, and may with advantage be substituted for carbolic acid wherever the use of the latter is indicated. They are much more soluble in water in all proportions, perfectly inodorous, and are so harmless that they may be applied even in a concentrated form to such sensitive organs as the eye. Dr. Le Bon recommends them as powerful disinfectants and for preserving meat and other alimentary substances. Before submitting these new agents to the Academy, Dr. Le Bon sent a quantity of meat slightly coated with them to La Plata, which they reached in as fresh a state as when they started from Paris.

A great deal has been said and written about the injurious effects of tobacco on the system, but these effects have been greatly exaggerated. There is no doubt that the excessive use of the weed is noxious, but its habitual employment in moderation is not so dangerous as anti-smokers endeavour to make out; for, when it is considered that about two-thirds at least of the inhabitants of the globe use tobacco in one form or other, there is every reason to believe that the charges against it are not quite justifiable. The bulletin of the Association Française against the use of tobacco contains a note by Dr. Piasecki, physician to the tobacco manu-

factory at Havre, on the effects of the weed on the women employed in the manufacture of cigars, &c. After a minute inquiry among the women of the establishment, 540 in number, Dr. Piasecki, has arrived at the following conclusions—that the manipulation of tobacco, even on such a large scale as is practised in the manufactory, had no pernicious influence on their general health, that they were not more subject to the maladies peculiar to their sex, nor was the mortality among them and their children greater than among women otherwise employed. Dr. Piasecki, however, adds, that a short time after their admission to the manufactory, the women generally complain of headache, giddiness, nausea, but they soon get accustomed to the work, and to the emanations of the tobacco, and continue their work without any further inconvenience.

Paris, October 24th, 1882.

## AN AMERICAN CONVALESCENT HOME.

(From a Roving Correspondent.)

THE first convalescent institution ever established for hospital purposes in America was opened on April 25th, 1882. It was founded by Miss Mary Russell, to whose devotion it owes much of its success. It is called the Waverley Convalescent Home, and is worked by the trustees of the Massachusetts General Hospital. Waverley is about seven miles from Boston, the country around is hilly and well wooded, and the site selected for the convalescent home is a singularly beautiful spot. With all the progressive genius for which the Americans are famed, for some unexplained reason they have not heretofore recognised the advantages of convalescent hospitals. I shall have more to say of the Massachusetts General Hospital on another occasion, and so need not refer further to it here. The Waverley Convalescent Home has been erected from a fund of 100,000 dollars, which was specially raised for this purpose, 30,000 dollars being spent on the buildings and furniture, and 70,000 dollars being invested as an endowment fund for the permanent maintenance of the Home. It contains thirty beds for patients, and has two wards of nine beds each, one with three beds, two with two beds, and four single-bedded rooms. The Home is intended mainly for the use of the patients at the Massachusetts General Hospital, and both free and paying patients may be admitted. The proportion of accommodation for paying to free patients is about one to five; but as the object of the trustees is first to benefit the poor who are unable to pay the expense of procuring fresh air and change, so far none but free patients have been received. This is remarkable, and shows how easily the combined pay and free system works in the general hospitals of America. Although the majority of the patients treated in the Massachusetts General Hospital pay something towards the cost of their maintenance during their residence within its walls, the trustees enact that the Convalescent Home shall be for the minority—i.e. the poor; no pay patient is admitted, and no difficulty whatever arises. The whole arrangements at the Waverley Home are admirable, and the cheerful and cleanly appearance of everything fills the visitor with gratification. Every ward, every room, every office, from roof to basement, is admirably arranged and perfectly kept. Indeed, I have never seen a more model institution than the Waverley Convalescent Home.

The sanitary arrangements have been very carefully planned. The w.c.'s and slop-sinks are on a new and very simple but excellent plan, and might with advantage be introduced into English hospitals. The closet consists of a simple glazed earthenware hopper fixed upon an S-pipe placed upon a floor of glazed white tiles. No wood-work whatever is used except the seat, two seats being fixed with hinges, one on each side of the pan, so that the same closet serves for nurses and patients. The nurses' lid is raised, fixed to the side, and locked, except when in use. The slop-sinks are large and of galvanised iron, being two feet in diameter at the top, so that they serve as urinals when necessary; they are also fixed on a tiled floor. The partitions between the closets are of wood; they are placed six inches above the floor, the doors to the closets being one foot above the floor at the bottom and louvered throughout. Thus all parts of the closets and lavatories can be washed

out with ease, there is no accumulation of dust or dirt, and all pipes are exposed. The woodwork and doors throughout the home are of pitch pine varnished, and the furniture is made of the same wood. This, the first American convalescent home, is well worth a visit, and I have little doubt many others will soon be erected. The plans and arrangements reflect great credit upon Dr. Whittemore, the able superintendent of the Massachusetts General Hospital, whose knowledge of hospital administration and the zeal with which he enters into his work must prove invaluable to the trustees.

## MEDICAL NOTES IN PARLIAMENT.

IN the House of Commons on Tuesday, on the motion of Mr. Dodson, the report to the President of the Local Government Board, by the inspectors appointed to inquire into certain deaths and injuries alleged to have been caused by vaccination at Norwich, was presented to Parliament. Captain Aylmer gave notice of a question as to the transport and commissariat arrangements during the Egyptian campaign.

On Wednesday, Sir R. Cross gave notice of two questions to the Home Secretary as to what steps are being taken under the Artisans' Dwellings Acts by the Metropolitan Board of Works and the Commissioners of Sewers of the City of London.

Mr. P. A. Taylor will inquire on Tuesday next of the President of the Local Government Board when the report of the Norwich vaccination inquiry will be in print.

Mr. Cochrane Patrick has given notice that next session he will call attention to the operation of the Factory Laws in Scotland.

## Medical News.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—The following gentlemen, having passed the required examination, received the Diploma in Dental Surgery at a meeting of the Board of Examiners on Wednesday last:—

Ackland, John M.K., Exeter.  
Albert, Henry Louis, Sloane-street.  
Andrew, John James, Belfast.  
Bate, Frederick William, Al-xander-road.  
Cornelius, William Fyer, Teignmouth.  
Edwards, Richard, Pontdolgoch.  
Gould, John Horace, Exeter.  
Hughes, Morgan, Redhill.  
Kisack, Frank Hill, Douglas, Isle of Man.  
Royston, Jonathan, Douglas, Isle of Man.  
Patterson, William Todd, Kingsland.  
Tester, Alfred Horace, Brighton.

One candidate was referred.

**UNIVERSITY OF CAMBRIDGE.**—The following Degrees have been conferred:—

M.D.—Charles Clement Lapage, Magdalen.  
M.B.—John Grissell Marshall, Clara.

The under-mentioned have passed the examination for the Certificate in Sanitary Science:—

D. S. Davies, M.B.; A. MacLachlan, M.D.; C. J. McNally, M.D.; T. Maxwell, M.D.; C. J. W. Meadows, M.R.C.S.; A. Penn, L.R.C.P.; S. M. Salaman, M.D.; Joseph Smith, M.R.C.S.; W. E. Steavenson, M.B.; J. A. Thompson, L.R.C.P.; Henry Smith, M.B.

The following Examiners have been appointed for the ensuing year: For the First M.B. Examination—Messrs. Main, Garrett, and Vines; for the Second M.B. Examination—Dr. Watney, Dr. Shuter, and Mr. Marshall; for the Third M.B. Examination—Drs. R. E. Thompson, Galabin, and Handfield Jones. Messrs. Luther Holden and Thos. Bryant have been appointed Examiners for Medical and Surgical Degrees, and Dr. Cheadle Assessor to the Regius Professor of Physic, during the ensuing year.

**COLLEGE OF PHYSICIANS IN IRELAND.**—The following Member of the College has been elected to the Fellowship:— John Henry Chapman.

The following gentlemen have been admitted Members of the College:—

Walter Charles Bourney, William Dyas, Frederick Ffolliott, William Henry O'Meara, John Alexander Scott.

At examinations held during October the following can-

didates obtained the Licences in Medicine and Midwifery of the College:—

**MEDICINE.**—Henry Adcock, John Mary Harrington, Thos. Chatterton Hitches, John Henry Jones, Claudius O'Donel, John Wm. White, William Henry Wright.  
**MIDWIFERY.**—Henry Adcock, William Hallaran Bennett, John Mary Harrington, Claudius O'Donel, John William White.

At a special examination held in September the following gentleman obtained the Diploma in Midwifery:—

John William Williams.

The following office-bearers have been elected for the ensuing year:— President: W. Moore. Vice-President: F. R. Cruise. Censors: F. R. Cruise, Arthur W. Foot, Fleetwood Churchill, and C. J. Nixon. Additional Examiners: G. F. Duffy, J. Magee Finny, A. V. Macan, C. J. Nixon, J. M. Purser, and W. G. Smith. Registrar: John W. Moore. Treasurer: Aquilla Smith. Examiners in Midwifery: J. R. Kirkpatrick and Stephen M. MacSwiney. Professor of Medical Jurisprudence: R. Travers. Representative on the General Medical Council: Aquilla Smith.

**APOTHECARIES' HALL.**—The following gentlemen passed the examination in the Science and Practice of Medicine, and received certificates to practise, on Oct. 19th:—

Jackson, Paul, Torrington, Devon.  
Schön, Charles Henry, Bridge, Canterbury.

The following gentleman also on the same day passed the Primary Professional Examination:—

Morgan, George, Charing-cross Hospital.

THE Poplar Hospital is to be opened for the reception of scarlet fever patients.

THE munificent legacy of £20,000 has been bequeathed to the Salop Infirmary by the late Mr. Henry Spence, merchant of Shrewsbury, who died on the 18th inst.

MR. THOMAS ASPINALL, L.R.C.P. Edin., of Over Darwen, has, we regret to learn, suffered serious injuries by being thrown from his trap.

THE Rowley Sanitary Authority have, in consequence of the prevalence of zymotic disease in the district, decided to provide an infectious disease hospital.

A MAN died last week in the Glasgow Infirmary from hydrophobia resulting from the bite of a rabid dog on March 14th last.

THE salary of Dr. Stevenson, medical officer of health for Paddington, has been increased from £300 to £400 a year.

THE balance of the proceeds of the recent Guild Festival at Preston amounts to £626, which it is proposed to hand over to the treasurer of the infirmary.

**CHARING-CROSS HOSPITAL MEDICAL SCHOOL.**—Mr. W. Morrison has obtained the first Entrance Scholarship of £30, and Mr. G. H. Biden the second Entrance Scholarship of £20.

THE foundation-stone of a new wing of the North-West London Hospital, in the Kentish-town-road, was laid on Tuesday by the Lady Mayoress. The subscriptions amounted to £285.

**VACCINATION GRANTS.**—The following gentlemen have received the Government grant for efficient vaccination:—Mr. W. Hood, M.R.C.S., L.S.A., City of York (second time); Mr. W. H. Hatfield, Hambleton District of the Droxford Union; and Mr. C. Lyddon, Oldbury.

A PLOT of land has been offered by the Hammer-smith Burial Board to the Fulham District Board of Works for £873, on which to erect a mortuary, a coroner's court, and a post-mortem room for the district. The offer has been accepted.

**HALIFAX MEDICO-CHIRURGICAL SOCIETY.**—A meeting of the practitioners of Halifax was held at the infirmary on Monday, Oct. 23rd, for the purpose of forming a Medico-Chirurgical Society for Halifax and its district. The chair was taken by Dr. Bullin. It was resolved to inaugurate a Society having for its leading features the distribution of medical periodicals, and the monthly reading of short practical papers, with exhibition of specimens. There cannot be a doubt as to the social influences for good of local societies.

**MANCHESTER SOUTHERN HOSPITAL.**—The annual meeting of the subscribers to this institution was held on Monday last, the Mayor of Manchester presiding. The report stated that 176 in-patients had been admitted during the past year, 3536 out-patients (women and children) relieved, and 332 poor married women had been visited by the medical officers. The expenditure had been £955, which was very nearly met by the receipts (£947).

**HOSPITAL SATURDAY FUND.**—No less a sum than £160 has been received from the Royal Arsenal, Woolwich, towards this fund, of which £101 was contributed by the Laboratory Department alone. The total collection at the Arsenal last year amounted only to £90. The receipts from the Post Office are also considerably in excess of 1881, amounting in the aggregate to £286. The workshop collections are still coming in satisfactorily, and thus far both in number and amount are generally in advance of those of preceding years. The time fixed for the reception of these collections, admitting of their inclusion in the present year's balance sheet, has been extended to the 18th of next month. Between thirty and forty different hospitals and dispensaries have intimated their willingness to receive representatives of the fund at their respective boards of management as life governors.—*Times*.

## ROYAL UNIVERSITY OF IRELAND.

M.D. DEGREE EXAMINATION.  
(Sept. 18th, 1882.—9.30 A.M. to 12.30 P.M.)

### ANATOMY.—(PASS.)

#### Section A.

1. Describe the nasal fossæ.
2. State precisely what are the relations of the right ureter in the male and female respectively.
3. Describe the necessary dissection to be made in order to expose the sphenopalatine ganglion.

#### Section B.

4. Describe the lymphatics of the inguinal region. Trace the course of the superficial and deep epigastric arteries, giving the relations and branches of the latter.
5. Give the boundaries of the fourth ventricle, and mention all the parts observed on its floor. What is the ligula?
6. Describe the arytenoid cartilages, and the ligaments connected with them.

(This examination comprised, besides, a dissection with an oral on the dead body and an oral on osteology.)

### ANATOMY.—(HONOURS.)

#### Section A.

1. Describe a dissection that will bring into view the malleus, incus, and stapes in position. (No description of parts is required.)
2. Give a detailed account of the movements of the knee-joint.

#### Section B.

3. Describe the intrinsic muscles of the tongue.
4. Give the position and vascular and nervous connexions of the coecal gland. Describe its appearance, size, and structure. (Also a dissection and oral on the dead body, &c.)

## Medical Appointments.

*Intimations for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning at the latest.*

- APPLEFORD, S. HERBERT, M.R.C.S., has been appointed a House-Physician at the London Hospital.
- BADDELEY, CHAS. EDW., M.B.Lond., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Gosnell District of the Newport (Salop) Union.
- BARLOW, THOS. CAREY, L.R.C.P.Ed., has been appointed Medical Officer to the Third District of the Hackney Union.
- CLENDINNEN, J. GEORGE, L.R.C.S.I., L.A.H.Dub., has been appointed Medical Officer of Health for the Lower Sedgley Urban Sanitary District, vice Eagleton, resigned.
- CROSS, FRANCIS RICHARDSON, M.B.Lond., F.R.C.S.Eng., has been appointed Honorary Surgeon to the Bristol Eye Hospital, vice Bartley, deceased.
- EASON, ALEXANDER M., L.R.C.P.Ed., L.R.C.S. Ed., has been appointed Medical Officer of the Talbot Clifton Friendly Society, and the Order of Druids, Lytham, vice William E. Pountney, M.D., resigned.
- FERRIS, JOHN SPENCER, M.B., L.R.C.P.Lond., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Denham District of the Eton Union.
- FINLAY, Rev. HUNTER, M.D., L.F.P.S.Glas., has been appointed Surgeon to the Hodgkinson District Hospital, Queensland.

GALE, A. K., M.R.C.S., late House-Surgeon to the London Hospital, has been appointed Assistant Medical Officer to the Fulham Fever Hospital.

HAYCROFT, CHARLES H., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Bow District of the Crediton Union.

KNIGHTS, Mr. JAMES WEST, has been appointed Public Analyst for the County of Huntingdon.

MACCARTHY, FFENNELL, M.B., B.Ch. Univ. Dub., has been appointed Surgeon to the Midland Railway, Worcester District, vice Geo. F. A. Knapp, M.R.C.S., deceased.

MACDONALD, ALEXANDER, L.R.C.P.Ed., L.R.C.S. Ed., has been appointed Medical Officer for the Kirkoswald District of the Penrith Union.

MACGILLIVRAY, CHARLES WATSON, M.D., F.R.C.S.E., has been appointed Assistant-Surgeon to the Royal Infirmary, Edinburgh.

PENRUDDOCKE, CHARLES, M.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer to the Vale District of the Winchcombe Union, vice Thos. Newman, M.R.C.S., L.S.A.Lond., deceased.

PRATT, JAMES, M.R.C.S., has been appointed Resident Medical Officer to the St. George, Hanover-square, Dispensary, vice F. Prince, M.R.C.S., resigned.

REYNOLDS, JAMES J., L.R.C.P.Lond., M.R.C.S., L.S.A.Lond., of Stoke-by-Clare, Suffolk, has been appointed Assistant-Surgeon to the Portland Convict Prison.

RYAN, JOHN, L.K.Q.C.P.I., L.R.C.S.I., has been appointed Medical Officer for the Second District of the Northleach Union.

THISTLE, FREDERICK T., L.R.C.P.Lond., M.R.C.S., has been appointed Senior House-Surgeon to the Torbay Hospital and Provident Dispensary, Torquay.

WILEY, ARTHUR ORMSBY, L.R.C.P.Ed., L.R.C.S.I., has been appointed Medical Officer for the Scriven District of the Knaresborough Union.

## Births, Marriages, and Deaths.

### BIRTHS.

ALLEN.—On the 12th inst., at Brunswick-terrace, Freeman-street, Grimsby, the wife of T. W. J. Allen, L.R.C.P.Lond., M.R.C.S.Eng., of a daughter.

ALLEN.—On the 20th inst., at Uxbridge-road, Shepherd's-bush, W., the wife of Thomas Allen, Surgeon, of a daughter.

BEVERIDGE.—On the 16th inst., at Dart Villa, Totnes, the wife of H. T. S. Beveridge, M.D.Edin., Staff-Surgeon, Royal Navy, of a daughter.

HUTCHINSON.—On the 29th August, at St. Kilda, Melbourne, Australia, the wife of B. C. Hutchinson, M.D., of a son.

JONES.—On the 14th inst., at North-park House, Harrogate, the wife of A. O. Jones, M.D., of a son.

MACNALT.—On the 16th inst., at Colton Old Vicarage, Greenod, Ulverston, the wife of Frank C. MacNalty, M.A., M.D.Dub. Univ., of a son.

RAVEN.—On the 19th inst., at Broadstairs, the wife of Thos. F. Raven, L.R.C.P., of a daughter.

SMITH.—On the 23rd inst., at Phillimore-terrace, the wife of W. Towers Smith, M.R.C.S., of a son.

### MARRIAGES.

BOTHAMLEY-SMITH.—On the 14th inst., at St. John's, Lewisham High-road, R. Broughton Bothamley, M.R.C.S., of Bromley, Kent, to Jeannetta Harrison, daughter of the late William Smith, of Southwark.

BULLOCK-SULIVAN.—On the 14th inst., at Holy Trinity, Bournemouth, Henry Bullock, F.R.C.S., of Overtown House, Spring Grove, Isleworth, to Sophia Henrietta, eldest daughter of Admiral Sir B. J. Sullivan, K.C.B., of Tregew, Bournemouth.

KENNEDY-HAYLE.—On the 17th inst., at St. Mary's, Rochdale, William A. Kennedy, M.B., L.R.C.P.Lond., son of the late Dr. J. F. Kennedy, of Newcastle-on-Tyne, to Sarah, third daughter of Thomas Hayle, M.D.Edin., of Rochdale.

POPE-PECKHAM.—On the 25th inst., at the Parish Church, Pinner, by the Rev. J. S. Lyon, assisted by the Rev. Dr. Pinnock, Vicar, Percy Pope, M.R.C.S., L.R.C.P., of Owston Ferry, Lincolnshire, youngest son of the late John Robinson Pope, M.R.C.S., L.S.A.Lond., of Woodridings, to Kate Florence, fourth daughter of the late Robert Peckham, Solicitor, of Doctors' Commons, and of Tottenham.

### DEATHS.

ANDERSON.—On the 22nd inst., at Hillingdon Heath, Uxbridge, William Alexander Anderson, M.D.Aber., F.R.C.S.Eng.

BROUGHTON.—On the 14th inst., at Ambleside, Francis Broughton, F.R.C.S., late of Her Majesty's Medical Service, Bombay, aged 62.

EDWARDS.—On the 13th inst., at his residence, Stony-hill, Colebrookdale, Shropshire, Benjamin Edwards, M.R.C.S., L.A.C., last surviving son of the late William Edwards, M.R.C.S., of Colebrookdale, aged 67.

HOLLIS.—On the 19th inst., at his residence, Alvaston, near Derby, William Hollis, Surgeon, aged 76.

PEARCE.—On the 5th inst., at Cadiz, of consumption, George A. C. Pearce, M.B., F.R.C.S., late of Dane's-inn, London, and Lee, Kent, aged 31.

WATERHOUSE.—On the 17th inst., at Peating Magna, Leicestershire, of enteric fever, Joseph Bourne Waterhouse, M.R.C.S., in his 30th year.

*N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

*Local papers containing reports or news-paragraphs should be marked.*

*Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."*

## A MUCH NEEDED IMPROVEMENT.

GREAT inconvenience is experienced by ladies in London by the absence from our streets of any sort of accommodation for them similar to that to be found in every principal thoroughfare for the use of gentlemen. With the exception of railway stations and a very few of the better class restaurants, no facilities are provided of the kind referred to for females, and any movement for supplying the deficiency is worthy of support. Such a movement is now on foot, promoted by Mrs. Emily Wilcox, of 189, King's-cross-road, who will be glad to receive subscriptions in aid of the scheme. This lady proposes to open an experimental retiring-room in the neighbourhood of King's-cross first, and, as the funds flow in, to increase the number by providing them at all crowded spots. The use of these places is to be open to all without charge, but a box will be provided in each for the reception of gratuities towards defraying the expenses. The scheme is a deserving one, and ought not to have been left to private enterprise by the parochial authorities. Probably, however, when once provided, the expense of keeping the rooms in a fit state for use will be undertaken by the local governing bodies. On hygienic grounds alone the proposal is deserving of success.

Kent.—F. H. Whymper, Esq., Factory Department, Whitehall.

## A CASE OF COMPLETE INVERSION OF THE UTERUS.

To the Editor of THE LANCET.

SIR,—The above is an accident which occurs so infrequently as to be worth a passing notice. I was called at 6.40 on Saturday morning, the 15th October, to see a married woman, aged twenty-six years. This was her third confinement. The child was born at half-past five, very rapidly. She was being attended to by a midwife, and I was sent for because there was something wrong about the after-birth. On my arrival I found the woman lying on her back on the floor, perfectly exsanguine and collapsed, and without pulse. The placenta was attached exactly in the centre of the fundus of the uterus, and it, still adherent, along with the whole of the uterus, lay between the legs of the woman; and the bed and clothes were completely saturated with blood. I peeled off the placenta, replaced the uterus, and tried to rally the woman, but she died from shock and hæmorrhage ten minutes after my arrival.

The history was as follows:—The woman was very anæmic; had a rupture of the perineum at her first labour; the midwife had pulled at the cord to separate the placenta from the uterus; and this last, along with the central position of the attachment of the placenta, which was firmly adherent, and the rupture of the perineum, had probably caused the complete inversion which I found.

I am, Sir, yours, &c.,

Crawshawbooth, Manchester, Oct. 1882.

J. L. KERR, M.B., &c.

## "A QUERY."

DR. PRATT, in reference to a note which appeared under this heading in our issue of Oct. 14th, writes to say that the cause of the discolouration referred to has been found to be an ointment used by the patient which was not official, and the composition of which was not known until after the note appeared in THE LANCET. This ointment produced a copious ink stain, which has disappeared from the dressings since the unguent has been discontinued.

Manchester should consult Mr. Burdett's book on Cottage Hospitals, published by Messrs. Churchill.

## "THE USE OF TOBACCO."

To the Editor of THE LANCET.

SIR,—Having been a regular and moderate, never at any time immoderate, smoker for the past twenty-five years, and having closely observed the effect of tobacco upon myself, you may possibly think the impressions I have formed worth recording. Even as a student I never smoked during the day, and have for seventeen or eighteen years smoked nothing but Cope's "mild Havannah" out of a briar-wood pipe, which I have frequently cleaned or changed. I should estimate my average is about four pipes of medium size every evening between 9 and 11 o'clock; cigars or cigarettes I rarely smoke. I consume five pounds of tobacco a year. About four years ago I began to suffer from severe nasal catarrh, which in a few months completely destroyed my sense of smell. I have not since then been able to smell or taste the smoke in the slightest degree. This misfortune has lessened my pleasure of smoking very much, and taken away much of the desire for it; but I still feel that I have missed something if I do not smoke at least one evening pipe.

Now, as to the effect of tobacco on the system. I am perfectly certain that it is the man with abundant nerve power who most keenly enjoys his pipe and is least harmed by it. The weary, the anxious, the worried do not enjoy or resort to smoking for the pleasure they derive, but for the tendency to tranquillisation and sleep they find it produces; in other words, it allays nervous irritability and diminishes the desire to energise. It has been stated that under its influence the heart's action becomes stronger. This is undoubtedly the case, but how is it explained? I think by the temporary disturbance of innervation by its action on the cardiac branches of the vagus. Three or four pipes of Cavendish tobacco would produce in me the irregular bounding of "tobacco heart," and cause me to wake up with a terrific nightmare. Here is increased action with irregularity of rhythm, but with depression the following morning. It has also been said to promote digestion. The after-dinner or luncheon pipe, so commonly taken, shows that it does so—but how? I think by tending to cause, by its effect on the controlling nervous influence, a more copious and immediate flow of gastric juice, and probably increasing the movements of the stomach, as undoubtedly it does that of the intestines, for thousands of men will tell you that a pipe after breakfast helps them in this respect without fail. Smokers to excess generally become of pale or sallow complexion, and occasionally of a slightly jaundiced hue; they are lethargic often in mind as well as body. This points to permanently lowered heart power, and as an example of its more immediate depressing influence following quickly on the transient period of "increased force," I may quote the case of an innkeeper, aged eighty-one, who was in the habit of beginning his evening smoke about 6 in the evening. During the year 1879 I was hastily summoned to him about 9 at night at least half a dozen times in consequence of his having fallen off his chair in a fainting fit. On each occasion he had quite recovered before I got to him. I found the cause clearly to be the effect of tobacco, and I persuaded the old man to puff at an empty pipe, which he did, and had no more syncope. To sum up, I am certain that the toxic effect of tobacco is to lower the nervous power, and, as a consequence, impair the circulation. It also tends to produce heavy lethargic sleep, which is followed by a disinclination to rise, and a feeling of weariness and low spirits, which the usual cold sponging tends to remove. The conflicting views held regarding its influence and effects are due, I feel sure, to the diverse symptoms it produces in different diatheses and temperaments and at different ages. I have met numerous cases, and am an instance myself, that in middle life men begin to feel that they cannot smoke as they formerly did, and they begin to limit themselves. Why is this? I think it is because as age advances we lose that large reserve of nervous power which in youth enables us to do much that we cannot do with impunity in middle life, and thus the depressing effect of tobacco is unfeeling in the days of exuberant and rapidly restored nerve power. I am speaking throughout, be it remembered, of strictly moderate smoking, for no one doubts the evil effects of excess.

If further proof be needed of the depressing effect of tobacco on the nervous centres, witness the almost immediate result when a half-drunken man smokes. It rapidly renders him helpless and more incoherent. Here I believe the nervous centres, already to a great extent paralysed by the alcohol, are very susceptible of the influence of tobacco. It has often occurred to me that the desire to drink stimulants, which undoubtedly accompanies the use of tobacco, is due as much to the nervous depression giving rise unconsciously to the feeling of need for stimulation as to the dryness or irritation of the mouth and fauces produced by the deposit of oil from the smoke. In this respect I regard tobacco as undoubtedly productive of much harm, as when using it the provocation to drink beer or spirits is certainly increased.

I remain, Sir, yours obediently,

October, 1882.

DELTA, M.D.

## NEW SYSTEM OF DROP-MEASURING.

A NOVELTY in pharmaceutical appliances has been patented by H. Lamprecht, of Marlenhütte (Hanover), in the shape of a drop-measuring bottle, which is specially constructed for that purpose. A leading German paper connected with the glass trade remarks that experiments made show that even with different ways of sloping the bottle, the drops are almost exactly equivalent in quantity.

*L.R.C.P. Lond.*—Some time ago it was stated that the German Chancellor had caused the announcement to be made that Duke Theodore of Bavaria, who had then taken the degree of Doctor of Medicine at a German University, had received a certificate enabling him to practise as a surgeon without being required to undergo the additional examination to which intending practitioners are ordinarily liable under the German law.

## TRICYCLES.

To the Editor of THE LANCET.

SIR,—Now that tricycles are happily coming so much into use, I will endeavour, through the medium of your valuable journal, to convey to my brother practitioners the result of my experience, which has extended over a period of upwards of ten years. Having made affections of the nervous system my pet study for many years, I have had much opportunity of testing the value of the tricycle, and I can confidently say if practitioners would give the subject their consideration, they will agree with me in regarding the machine as a remedial agent of great value. Cases are continually coming under our notice which require, in addition to medical treatment, exercise in the pure, fresh air, by which the brain and nervous system become invigorated, and the sufferer is relieved from that irritable feeling which can only be understood by those who suffer from it; and need I also say by this means the general muscular system is strengthened, including a vast number of muscles which are not called into action by the ordinary walking exercise. This fact is borne out by tricycle riders, who declare they can walk much better than they could before they took to tricycle riding. Of course I am fully aware walking exercise is exceedingly good—quite in accordance with nature's laws in a vast number of cases, but I have generally found those of my patients who try to walk frequently complain of much weariness and exhaustion, which is no doubt attributable in a great measure to the fact of the mind not being diverted, as in the case of horse or tricycle-riding. Some time since one of your correspondents called attention to the tendency in those who use this kind of locomotion to contraction of the chest by leaning forward on the handles of the machine. This is chiefly confined to timid and inexperienced riders; nevertheless it should be remedied, and this can easily be done by having the handles of the tricycle put farther back. The effect of this modification may be easily tested by sitting in one's chair in the same position as on the tricycle, placing the hands under the seat and drawing them back, which will bring the body into an erect posture, and throw the shoulders back and the chest forward. I propose to bring this point under the notice of the makers, with suggestions how to effect the improvements indicated. As to the question of the advisability of females riding tricycles, though at first I entertained serious doubts on the matter, I have from experience come to the conviction that females need have no fear; on the contrary, some who have long suffered from internal troubles have derived much benefit from this mode of exercise, especially in the class of cases where the system has fallen below par by long continued confinement. Again, with regard to the tendency of tricycle-riding to produce hernia, in no instance has it done so under my observation. Indeed, a gentleman who for many years had suffered from very large double inguinal hernia tells me he owes his present good health to this form of exercise, and does not feel the least inconvenience from his affliction, and has upon advanced in life he continues his daily rides, wet or fine, and has up to the present time ridden very considerably above 50,000 miles. Riders should not attempt too much at once, but steadily continue the daily use of the machine, and by degrees, as the muscles develop themselves and the nerves get tone, they will find all difficulties pass away. In concluding, I would advise intending riders to try various machines before purchasing, and judge for themselves.

Oct. 1882.

I am, Sir, yours, &c.,

ONE WHO ADVOCATES EXERCISE IN  
THE PURE AIR.

## TEMPERATURE AT SAN REMO.

To the Editor of THE LANCET.

SIR,—I enclose a report of the weather and temperature here for the week just finished, which may be interesting to some of your readers.

I am, Sir, yours faithfully

L. E. KAY SHUTTLEWORTH.

Villa Calcagno, San Remo, Italy, Oct. 22nd, 1882.

	Maximum.	Minimum.	Difference.	Temp.
				8.30 A.M.
Mean for the week ..	65°	52°	13°	57°
Highest on any day ..	68°	55°	13°	59°
Lowest on any day ..	63°	49°	14°	55°

Two days cloudless, four bright sun and light clouds, two marked almost cloudless, one cloudy. No rain fell this week, and the wind was very light—sometimes none could be felt.

## SWISS FACTORY LEGISLATION.

ACCORDING to the report of the Swiss factory inspectors, the cantonal authorities of Glarus issued directions last year to the factories within their jurisdiction, that all accidents which cause more than six days' absence from work on the part of the person injured should in future be notified to the authorities. The object of this regulation is stated to be the frustration of attempts which are sometimes made to keep accidents from the knowledge of the officials, whose duty it would be to make an investigation into the circumstances.

*Mr. W. J. Masson.*—In almost every number of THE LANCET during the last two years some observation has been recorded of the association of acute specific diseases with organisms, but the causal relation has been proved in very few instances, although probably, by analogy, in all. It has not yet been proved in the case of scarlet fever.

## TRIAL BY JURY.

To the Editor of THE LANCET.

SIR,—May I ask you to give publicity to the following case, in the interest of the unfortunate victim.

Mrs. Dodsworth was arraigned at the Winchester Sessions, held on the 17th inst., on a charge of having taken poison at Bournemouth, on July 25th, with intent to injure herself. There was no defence, the defendant, who is an old woman over seventy, never asking a question. The case was clearly proven, and the magistrate, in summing up, concluded:—"You have now to determine whether this poor woman took the poison with the intent of doing herself grievous bodily harm," or words to that effect. After a few minutes' consultation, the foreman declared that they had come to an opinion, but they would like to add a rider. They were told to give their verdict first. Verdict was accordingly given, "Guilty." Now for the rider: "But we think she did not know what she was doing." The magistrate here remarked that if that was their opinion they should have given a verdict of not guilty, "but," he added, "there has been no evidence whatever brought to show you that she was of unsound mind; however, the doctor is in court, would you like to ask him any questions?" "Oh, I come from Bournemouth!" exclaimed a juror, and this appears to have been convincing, for, without more ado, a verdict of "Not Guilty, on the ground of insanity," was returned. The prisoner was, therefore, informed that she would be detained during Her Majesty's pleasure, and was removed in tears.

Now, the facts of the case are briefly these:—Mrs. Dodsworth has been living in Bournemouth for some months, having been placed by friends under the care of a woman who rents a house in a poor neighbourhood. She is, I think, over seventy years old, and has been in very good circumstances, rich and well connected. Of this I am assured by people who have known her friends in York. She has been much weighed down by the change in her affairs, has become peevish, and, it is said, addicted more or less to drinking. These things, added to her habit of dwelling on her former circumstances, and her eccentric costume of faded finery, have no doubt led to the opinion held by the poor people among whom she lived, and subsequently by the jury, that she was of unsound mind. But such I am sure is not the case, for I have attended her here and at her house for some time, and though I have seen that she is of weak intellect, yet she has always been quite mistress of her deeds, and always able to go about and collect recommendation-tickets to ensure her attendance, &c. At the time she attempted her life she had been depressed by having to leave her lodgings and other circumstances, but her subsequent conduct was perfectly rational. She submitted readily to treatment, merely saying in excuse, "I wanted to go to Heaven."

What I wish to point out is that in the mistaken idea that they would be doing a kindness, the jury have condemned this poor old woman to pass the remainder of her life in a lunatic asylum, whereas had they returned a verdict of guilty, the magistrate, taking into consideration that she had been already kept in prison nearly three months, would probably have let her off with a short additional term of imprisonment. Trusting that, by thus giving the case publicity, something may yet be done to alleviate her fate.

I remain, Sir, yours sincerely,

G. S. MAHOMED.

Bournemouth Dispensary and Cottage Hospital,  
Oct. 23rd, 1882.

*Freshman* should apply to the Secretary of the College for the details. The regulations are in force.

*Dr. Newham.*—We congratulate our correspondent on the dénouement.

## "BELLADONNA POISONING."

To the Editor of THE LANCET.

SIR,—Let me add a case of the above, not the result of accident however. When I was a resident physician's assistant at the hospital, we had a very intractable case of sciatica, and the physician in charge determined to try the subcutaneous injection of atropia sulph. The amount given was one-eighth of a grain, a friend of my physician stating that he had on several occasions administered that amount, with no ill-consequences, and with uniform success. Our patient's symptoms consisted of dilated pupils, thirst, dryness of fauces, frequent desire to pass water, with a lively delirium. These all passed off without treatment in about eight hours, leaving the patient cured of his sciatica. We all resolved to try a little less atropia next time.

I am, Sir, yours truly,

Oct. 22nd, 1882.

G. G.

## THE DERIVATION OF THE WORD "DRUGGIST."

A GERMAN CONTEMPORARY calls attention to the fact that this word can be traced to the root "trocken," which signifies in German "dry." The same derivation is ascribed to the equivalents of the word in various European languages.

*Enquirer.*—Dr. William Woods Bradshawe was an old member of the College of Surgeons. He was subsequently elected a Fellow of the College, and, we believe, was Mayor of Reading. His widow left £1000 each to the Royal Colleges of Physicians and Surgeons, and Sir James Paget is the first appointed Bradshawe Lecturer at the College of Surgeons.

*Forceps.*—Never is practically for all time, and A would "never" be justified in practising in the town or neighbourhood without B's consent.

## POISONING BY SHELL FISH.

To the Editor of THE LANCET.

SIR,—I enclose the notes of a case which recently occurred in my practice, and which may be of interest to some of your readers.

On Monday evening I received an urgent message to attend at once on a family in this village who had been taken seriously ill after having tea. The messenger informed me that they had all (herself included) partaken freely of crab, and had been taken with similar symptoms, which only varied in intensity. On arrival I found four sufferers, three of whom were ghastly pale, the fourth being the mother, who was fast recovering. Two daughters and the son were suffering most severely, the symptoms presented being great pain at the epigastrium, and violent vomiting, which was at first incessant, consisting of frothy mucus and particles of the fish and other contents of the stomach. The skin was cold and clammy, pulse very feeble, and in the son scarcely perceptible, as well as in the oldest daughter. The face was covered with a cold sweat, and the two latter cases seemed quite exhausted. Purgings was not present. The other daughter did not seem so much affected, although she vomited freely. The treatment I adopted was the giving of carbonate of ammonia in ten grain doses, hot-water bottle to the epigastrium and to the feet, with a mustard-plaster to the calf of the legs, and enveloping in blankets and putting them all to bed. The vomiting only recurred twice afterwards in the son and once in the oldest girl; not at all in the other cases. They slept fairly during the night. Next morning, with the exception of feeling weak, they did not seem any the worse. The patients being adults, it struck me whether the case would have ended so satisfactorily in children.

I am, Sir, your obedient servant,  
Great Ayton, Yorkshire, Oct. 17th, 1882. P. A. R., L.S.A. Lond.

*L. D. S.*—The examination for the Licence in Dental Surgery has just concluded. The calendar of the College of Surgeons contains the names of 510 licentiates in dental surgery.

*Minimo Minor.*—We fear our correspondent has no legal claim to a pension.

*Mr. Aston Ayres and An Old Practitioner.*—The matter shall have attention.

## THE INTRA-VENOUS INJECTION OF FLUID IN SEVERE HEMORRHAGE.

To the Editor of THE LANCET.

SIR,—In reply to Mr. Jennings I beg to state that I do not use the obstetric syringe for any of the purposes named in his letter. The perchloride of iron may be applied at least as effectively with a sponge, and, consequently, had not the idea of its having been so used in my mind. Water, salt, and brandy would, I believe, answer quite as well as Mr. Jennings's formula, and these things possess the great advantage of being always at hand. By care the entrance of air might be prevented, and the uniformity of the current insured. If however, the syringe has been so used, and unprovided with another, an ordinary glass one, which could be obtained at any druggist's, would do quite well. It is highly desirable that the appliances of our art should not be unnecessarily multiplied, and that the mind should be furnished with ready methods for emergencies.

I am, Sir, yours faithfully,  
Leeds, Oct. 23rd, 1882. PHILIP FOSTER.

*D. S. J.*—The Hunterian Oration will be delivered in February next, by Mr. Spencer Wells, the President of the College. Dr. Matthew Ballie, one of the executors of John Hunter, died Sept. 23rd, 1823.

*Psychologist.*—By reference to the general index of Boswell's Life of Johnson, it will be found that Dr. Thomas Arnold wrote on Insanity.

*A Puzzled Practitioner and F. C.*—No card enclosed.

## INUNCTION IN SCARLATINA.

To the Editor of THE LANCET.

SIR,—For a considerable time I have used free rubbing-in of camphorated oil in every case of scarlatina which I have treated, during the eruptive stage as well as during peeling. I was congratulating myself on the results, when a medical friend of considerable experience expressed to me his opinion that this use of oil has a bad effect upon the kidneys. If you, or any of your readers, can throw any light upon the question thus raised it will confer a favour, which will be much valued.

I am, Sir, yours faithfully,  
October 25th, 1882. CUTIS.

## A COLONIAL SURGICAL APPOINTMENT.

WE are asked to state that the office of resident surgeon of the Provincial Hospital at Port Elizabeth, Cape Colony, has been filled up by the appointment of a colonist.

*Students (Galway).*—The International Scientific Treatises of Messrs. King and Co., London, would probably include some that would suit our correspondent. Any bookseller would procure a list for him from Messrs. King and Co. (Rex and Co.), Gracechurch-street, London.

## SURGICAL CURIOSITY.

To the Editor of THE LANCET.

SIR,—An interesting case came under my notice about five weeks back. While examining the out-patients at the Stanley Hospital, a youth of twelve appeared with a tumour the size of a small marble, situated in his auricular lobule, just below the antitragus. I took it to be an ordinary cyst, despite the unusual site, and at once proceeded to remove it. This was easily accomplished, and on making an incision into it afterwards I discovered, in addition to some albuminous fluid, a grain of corn firmly embedded in a second cyst, which was attached to the internal aspect of the first. Five years previously the lad cut his ear on the site of the tumour. It healed in the usual way, and until two years back nothing disturbed it. From that time he noticed a small, pea-like body in the lobule, which thence described the usual symptoms accompanying the growth of a cyst. This case is interesting as a surgical curiosity, being I believe unique.

I am, Sir, yours sincerely,  
ROBERT JONES, M.R.C.S. Eng.  
Nelson-street, Great George-square, Liverpool,  
Oct. 20th, 1882.

*Mr. Matthew Hunter.*—Thanks. Our arrangements in the matter are, however, for the present complete.

*Student.*—The instrument is, and we should think must always be, untrustworthy.

*R. W. W.*—It would have no effect as regards its physiological action.

## DEFORMITY OF THE FOOT.

To the Editor of THE LANCET.

SIR,—The particulars of the following case may be interesting, as it is, I believe, an unusual deformity, and serves to illustrate, perhaps, our origin from a lower scale.

I was called to see a female child, born the previous day; on examining the child I found the right leg was about an inch and a quarter shorter than the left, the shortening being more marked in the tibia than the femur. The two outer toes were absent, as well as the metatarsal bones and, I believe, the cuboid; there was no external malleolus, but there appeared to be a head to the fibula, and the fibula then seemed to taper downwards until it was lost by, I believe, ankylosis in the tibia. The tibia was raised up and generally thickened at about the junction of the middle with the lower third, like a badly-united fracture, and the skin at this point was puckered in, as though there had been a compound fracture. The foot was turned outwards, the malleolus projecting very much, giving the foot the appearance of flat foot. I could obtain no family history of deformity, or of any fright during pregnancy. The child was otherwise healthy.—I am, Sir, yours &c.,

D'ARCY SUGDEN, L.R.C.P. Lond.,  
Resident Surgeon, Maryborough Hospital, Queensland.  
Oct. 25th, 1882.

*W. W.*—We are not acquainted with a work specially devoted to the subject. It has, however, been discussed from time to time in our columns, and will probably be referred to again in our next issue.

*Rev. J. W. Elliott.*—We recollect no later deliverance on the subject than that of Dr. Poore in the Bradshawe lecture in September last year.

*Mr. J. P. Pye.*—We regret that we have not space for more letters on the subject.

## HAMMAMELIS VIRGINICA.

To the Editor of THE LANCET.

SIR,—Can you or any of your readers inform me if there is any formula for the preparation of the tincture of hammamelis virginica; also, if they have tried the tincture as an injection for piles, if it is painful or successful.

I am, Sir, yours truly,  
October 25th, 1882. C.

\* Several letters respecting this drug appeared in THE LANCET of August 30th, 1879.—ED. L.

*Alumnus* should write to the Secretary of the College for the regulations concerning the prize. Only members, however, can compete.

*Mr. Aubrey Wicks.*—There does not appear to be any novelty in the suggestion.

## POSTAL MICROSCOPICAL SOCIETY.

To the Editor of THE LANCET.

SIR,—I should be glad if any of your readers could inform me through the medium of your columns whether the above named society is still in existence. If it is, I should be glad to join it.

I am, Sir, yours &c.,  
October 25th, 1882. HISTOLOGIST.

## POPULATION OF EUROPEAN CITIES.

ACCORDING to a comprehensive statistical return lately published in Germany, there are in Europe 92 cities with more than 100,000 inhabitants, out of which four capitals show each over a million population, as follows:—London, 3,832,440; Paris, 2,225,910; Berlin, 1,122,500; Vienna, 1,103,110. Out of the 92 cities and towns alluded to, England claims 26, Germany 16, Italy 11, France 10, and Russia 8. The others are divided amongst the smaller states.

ERRATUM.—In our article of the 7th inst. on the treatment of the sick and wounded in Egypt, the name of Mr. Harrison, Surgeon of the Grenadier Guards, was erroneously given as Gardner.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Professor Acland, Oxford; Mr. Campbell, London; Dr. Spencer Thomson; Mr. Hawkins-Ambler, Leeds; Mr. Hunter; Mr. Neville Stephen, Marseilles; Mr. Duncan Miller, London; Mr. Farren, Carnarvon; Dr. Philip Foster, Leeds; Mrs. Wilcox, London; Mr. Shuttleworth, San Remo; Mr. Mason, Herne-hill; Mr. W. Thomson, Melbourne; Mr. Courtenay, Victoria; Mr. Wheeler; Brigade-Surgeon MacDowall, Deesa; Mr. Charles Mills, London; Dr. Ross; Mr. Isaac Williams, London; Mr. Deane; Dr. H. Rayner; Mr. J. C. Lucas, Ahmedabad; Mr. H. Rogers-Tillstone, Brighton; Mr. Walter Rivington, London; Mr. Peach, Bath; Mr. Brown, New Wandsworth; Mr. Luke, Calcutta; Mr. Hall; Mr. Unsworth, Liverpool; Messrs. Evans and Co., Liverpool; Mr. Tomlins, Rugeley; Messrs. Woolley and Co., Manchester; Mr. Roper, Croydon; Mr. Kirkpatrick, Woodbridge; Mr. Quinton, Norwich; Mr. Storey, Cheltenham; Dr. Brodie, Wickham Market; Mr. Horne, Scarborough; Mrs. Chatty, Dawlish; Mr. Maddox, London; Dr. Percy Boulton, London; Dr. Mackintosh, Chesterfield; Dr. Henderson, London; Mr. W. G. Balfour, Walton; Mr. T. Dolan, Halifax; Mr. Dacre Fox, Manchester; Dr. Herbert Stowers, London; Mr. Symonds, Oxford; Dr. Wortabel, Beyrout; Mr. Ayres, Brighton; Dr. Pye, Galway; H.; Medicus, Shrewsbury; R. W. W.; Forceps; Kent; Delta; Studens; Bookworm; L.R.C.P. Ed.; Theta, Dundee; An Old Practitioner; Glasgow; G. G.; W. W.; D. M., Manchester; Catis; C.; Minimo Minor; &c. &c.

LETTERS, each with enclosure, are also acknowledged from—Mr. Smith, Ealing; Mr. Woodcock, Bradford; Messrs. Ward and Son, Brompton; Dr. Williams, London; Dr. Tomkins, Monsall; Mr. North, York; Mr. Lovegrove, Wallerton; Mr. Mayland, Glasgow; Mr. Townsend, Exeter; Mr. Byfield; Mr. White, Bayswater; Messrs. Millikin and Down; Mrs. Took, Great Berkhamstead; Messrs. Barker and Co., Huddersfield; Mr. Rouse, Bayswater; Mr. Pope, Pinner; Mr. Gee, Southwell; Mr. Whitley, Halifax; Mr. Lask, Hingham; Dr. Powell, Newcastle-on-Tyne; Mr. Edmunds, Chesterfield; Dr. Thomas, Christchurch, New Zealand; Dr. Foote, Rotherham; Dr. Miller, Reading; Dr. C. Hewett, London; Mr. Pile, Salisbury; Dr. Allen, Grimsby; X.; Surgeon-Major, Dublin; M. P. D., Liverpool; J. G., Bloomsbury; Assistant, Liverpool; Medicus, Dartmouth park; Tenax, London; Principal, Seaford; Perilas, Exeter; L. C.; Beta, Manchester; C.; M. Z.; Home; Miss H., Oldham; Medical, Castleford; A. B.; J. R., Fence Houses; Albus, Holborn; E. F.; Medicus, Nottingham; G., Manchester; Principal, Seaford; Tenax Propositi; W.; A. B.; D. T., St. Helens; Alpha, Farringdon; C. R., Wandsworth; A. G. K., St. John's-wood; X. Y. Z., London; Medicus, Margate; C. J. A.; K. A., Clapham; F.R.C.S., Leeds; A. B. C., Paddington; H. F. D.; Medicus, Liverpool; Medicus, Birmingham; Medicus, Milford Haven; &c. &c.

Parkstone Reminder, Carnarvon and Denbigh Herald, St. Pancras Gazette, &c., have been received.

## Medical Diary for the ensuing Week.

## Monday, Oct. 30.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10½ A.M. each day, and at the same hour.  
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M. each day, and at the same hour.  
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.  
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.  
ST. MARK'S HOSPITAL.—Operations, 2 P.M.; on Tuesday, 9 A.M.  
MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. C. Theodore Williams, "On a Case of Paracentesis Pulmonia."—Dr. Leonard W. Sedgwick will communicate a paper by Dr. Richard Schmitz (Neuenahr), "On 600 Cases of Diabetes Mellitus."

## Tuesday, Oct. 31.

GUY'S HOSPITAL.—Operations, 1½ P.M., and on Friday at the same hour.  
WESTMINSTER HOSPITAL.—Operations, 2 P.M.  
WEST LONDON HOSPITAL.—Operations, 3 P.M.

## Wednesday, Nov. 1.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.  
MIDDLESEX HOSPITAL.—Operations, 1 P.M.  
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.  
ST. THOMAS'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.  
ST. MARY'S HOSPITAL.—Operations, 1½ P.M.  
LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.  
GREAT NORTHERN HOSPITAL.—Operations, 2 P.M.  
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2½ P.M.  
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at the same hour.—Skin Department: 1.45 P.M., and on Saturday at 9.15 A.M.  
EPIDEMIOLOGICAL SOCIETY OF LONDON.—8 P.M. Dr. Norman Chevers, "On the Sanitary Defects of the Site of London and its Suburbs."  
OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown by Mr. Alban Doran and others.—Dr. Champneys, "On a Description of a Kyphotic Pelvis, with remarks on Breisky's Description."—Dr. Matthews Duncan, "On Puerperal Diabetes."—Dr. Chahbazian, "On the Treatment of Post-partum Hemorrhage by Subcutaneous Injection of Ergotinine."

## Thursday, Nov. 2.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.  
ST. BARTHOLOMEW'S HOSPITAL.—1½ P.M. Surgical Consultations.  
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.  
CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and on Friday at the same hour.  
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M.  
NORTH-WEST LONDON HOSPITAL.—Operations, 2½ P.M.  
HARVEIAN SOCIETY.—8.30 P.M. Mr. Malcolm Morris, "On Chronic Ringworm."—Dr. Broadbent, "On some Points relating to the Sounds of the Heart."

## Friday, Nov. 3.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1½ P.M.  
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 2 P.M.  
ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.  
KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.

## Saturday, Nov. 4.

KING'S COLLEGE HOSPITAL.—Operations, 1 P.M.  
ROYAL FREE HOSPITAL.—Operations, 2 P.M.

## SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year ..... £1 12 6 | Six Months ..... £0 16 8

TO CHINA AND INDIA ..... One Year, 1 16 10

TO THE COLONIES AND UNITED STATES.. Ditto, 1 14 8

Post Office Orders should be addressed to JOHN CROFT, THE LANCET Office, 423, Strand, London, and made payable at the Post Office, Charing-cross.

Notices of Births, Marriages, and Deaths are charged five shillings.  
Cheques to be crossed "London and Westminster Bank."

## ADVERTISING.

The Publisher cannot hold himself responsible for the return of testimonials, &c., sent to the office in reply to advertisements; copies only should be forwarded.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on page 2, which not only affords a ready means of finding any notice, but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance. Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed. Advertisements are now received at all Messrs. W. H. Smith and Sons' Railway Bookstalls throughout the United Kingdom, and all other Advertising Agents.

Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher.

Agent for the Advertising Department in France—J. ASTIER, 67, Rue Caumartin, Paris.

# Introductory Lecture TO THE COURSE OF SURGERY IN THE UNIVERSITY OF EDINBURGH.

*Delivered Oct. 24th, 1882.*

By JOHN CHIENE, M.D. EDIN.,  
PROFESSOR OF SURGERY IN THE UNIVERSITY.

(Continued from p. 698.)

I WOULD now direct your attention to a paper by Joseph Lister, in THE LANCET, March 16th, 1867. The paper is entitled, "A New Method of Treating Compound Fractures; Abscesses, &c." Lister, in this his first paper, on the subject, gives us the keynote to the position which he then took up, and to which he has ever since strictly adhered. In that paper, after pointing out that the decomposition which occurs in a compound fracture is due to the access of the atmosphere, he says, "We find that a flood of light has been thrown upon this most important subject by the philosophic researches of M. Pasteur, who has demonstrated, by thoroughly convincing evidence, that it is not to its oxygen, or to any of its gaseous constituents, but to minute particles suspended in it, long regarded as merely accidental concomitants of putrescence, but now shown by Pasteur to be its essential cause." He then adds, "All that is requisite is to dress the wound with some material capable of killing these septic germs." Here, then, it will be noted that Lister from the first adopted Pasteur's law as the basis of his practice, and having adopted this law, he then searched out a substance by which he hoped to attain his object. He tells us that in 1864 he was much struck by the advantages obtained by mixing carbolic acid with the sewage of the town of Carlisle. This knowledge encouraged him to try carbolic acid. It is not my intention to dwell upon the gradual development of the practical details. In March, 1865, Lister made his first attempt to form an antiseptic crust, using lint soaked in carbolic acid. This was a failure. After many anxieties and by learning a good deal more from his mistakes than from his successes, always steadfastly holding to the primary doctrine, he experimented first in Glasgow and then in Edinburgh, until in 1871 he elaborated that dressing which is now associated with his name. During all these years Lister was doing a double work; he was trying to perfect the practical details, while he was at the same time working at the germ theory, and doing very much to strengthen the scientific basis of his practice. Many are now working at the practical details. The theory has now become a law. New antiseptics are being daily introduced, and when a more reliable one than carbolic acid for general use has been discovered, no one will more gladly use it than Lister. Much harm has been done by calling his method of treatment the "carbolic acid method," the sole object which he has always had in view being not the use of any special antiseptic or any special plan of treatment, but a method which will enable the surgeon to keep his wound aseptic, from the time it is inflicted until healing has taken place.

It will perhaps be as well here to tell you that in the treatment of wounds their asepticity is only one part of the problem which the practical surgeon has to consider. Lister found that the silk ligature was a source of irritation, and hence arose the reintroduction by him of the catgut ligature. The presence of pus in an aseptic wound directed his attention to suppuration caused by tension—altogether apart from putrefaction—hence the application of free drainage to all wounds and the avoidance of suppuration from tension. The catgut ligature and free drainage directly were the outcome of a study of aseptic wounds. Do not be led into the too common error that Lister's reputation rests only on his application of Pasteur's law to surgery. His work is threefold in its strength. Do not imagine that a surgeon, in accepting Lister's teaching regarding antiseptics, thereby necessarily forgets the words of John Hunter: "The first and great requisite to the restoration of an injured part is rest." Many of the most valuable improvements that have benefited

No. 3088.

mankind have been the result of years of patient and prolonged investigation. These investigations have followed two great lines; the practical man, working by experience and observation, and gradually arriving at some idea of what should be, thinking little of the why; the scientific man, with Bacon as his model, experiment as his mistress, working little by little without any idea of the practical value of his investigations, wading like the practical mind through errors and mistakes, correcting them himself, or having them corrected for him by a future worker, until at last a time is reached when the lines of thought approach one another; then a master-mind, necessarily with both practical and scientific knowledge, able to estimate at their proper worth the value of the sum total of both lines of workers, grasps the double work, and although at first seeing dimly, he steadfastly perseveres until at last he is enabled to establish some great law which will in the future enable the practical mind to work more intelligently, the scientific mind gaining at the same time encouragement to work on, with the knowledge that each little portion of truthful scientific work will in the future bring forth practical fruit. We have a good example of this in the history of the science of astronomy. After Copernicus had shown that the sun is the centre of our universe, Kepler, by a series of calculations demonstrated the elliptical pathway of the planet Mars. A hundred years after, Newton demonstrated the reason why the planet Mars could only move in an ellipse, and showed how all the other planets necessarily followed the same law. It is well known how Adams and Leverrier, using Newton's laws, and working in their studies, told the practical astronomer that if on a certain night he would look in a certain part of the heavens he would see a new planet, which we now call Neptune. While Jenner, by acute observation, discovered vaccination, so we now find Greenfield and Pasteur working on the basis of Pasteur's law of fermentation, and demonstrating by experiment that the bacillus anthracis, which is the cause of splenic fever, can, if modified by cultivation, be inoculated into healthy animals, and give rise in them to a condition which may strictly be likened to the vaccine fever, and which prevents in them the fatal splenic fever, just as the vaccine fever prevents the fatal small-pox.

If such results have been already obtained by careful experiment, is it not legitimate to expect that before long some general law may be discovered by which the poison germs of other scourges, more nearly allied to ourselves, may be modified so as to enable us to limit in no small degree the dire effects of scarlet fever, typhus, cholera, &c.? Pasteur's law, in consequence of Lister's application, has had a revolutionary influence on surgery, there is now good evidence before us that it is doing the same for obstetrics and medicine. Do we not, as citizens, learn from what I have said to-day that it is our duty and our interest to encourage scientific work? I can imagine a visit to Pasteur's laboratory about the year 1860 by a hard-headed successful man of business, who, judging by immediate results—a rapid turn over being the essence of successful trade—would certainly ask himself the question, What possible practical good can ever come to me or to my children from this investigation? As certainly do I feel that, in this utilitarian and practical age, he would leave that laboratory impressed with the waste of energy displayed, while he would assuredly admire the patience and perseverance of the investigator. I ask this same man to go with me at the present day into an operating theatre, and he will undoubtedly, in all that he sees, be carried back to that former visit, and he will be the first to acknowledge that his former estimate was essentially short-sighted and hasty. If our countrymen could only be persuaded of the great immunity from pain, and the comparative freedom from danger which they can now command, and if it has been demonstrated that these results are directly due to scientific work, based upon experiment, then they would most certainly do everything in their power to aid in fostering the work and encouraging the worker. It must be a law that every truth will in the future bear good fruit. Let each one present remember that "we are all working together for one end, some with knowledge and design, and others without knowing what they do."

What lesson do we learn as workers from what I have said to-day? Let some time be given to the culture of the reasoning faculties, devote a certain portion of each day to self-instruction, self-questioning. Let each of us do a little piece of truthful individual work. Make a start; begin at once; get into the way of doing some special work, and like

any habit—good as well as bad—it will grow upon you. If of a practical turn, you will work by experience and observation; if of a scientific turn, you will work by experiment. Both have their value; and even if you only take up the rôle of an overturner of false doctrine, or even a critic of true doctrine, you will all have your use, as Marcus Aurelius says: "Men co-operate after different fashions, and even those co-operate abundantly who find fault with what happens, and those who try to oppose it and to hinder it, for the universe hath need even of such men as these."

One word of warning. The simple treatment of a wound with water dressing was, we now know, imperfect; still the majority were satisfied. Accidents, local and constitutional, were smoothed off and excused by the too common phrase, We had done our best. Let us take care that we do not fall into this error with regard to our present work. As you work, be sure to fight against any temptation which may encourage you to suppose that our knowledge is now perfect. Perfection is not of this world. Is it too much to ask for encouragement for individual work? Some years ago I tried to show that our extra-mural school—a most important factor in our system of medical education—owes very much of its success to the encouragement which is given to the individuality of its teachers, everyone of whom has chosen that subject to which he has devoted special attention. May I now say a word for the individuality of the taught? May I plead toleration and assistance for the man who desires to develop his mental individuality, who desires to concentrate his mind on some special piece of work? There is need for someone to speak out, to "use plain discourse," and to say, that if the public are to require of every candidate for any public duty a universal knowledge, the acquiring of which needs all his energies, then any power which he may originally have had of doing some special work—his individuality, his physical and mental personality—will be crushed out of him. Even our schoolboys are nowadays required to pass a certain standard, the examination system is in full force even in our infant schools. Would we not have more "lucidity" if the growth of our intellects was less fettered, simply directed, rather than pruned and trimmed, ordered to do this, forbidden to do that? Any unnecessary interference with the taught at once tells on the usefulness of the teacher. What opportunity have our schoolmasters to develop any special talent in their pupil when their energies are fully occupied in polishing all their material—good, bad, and indifferent—to one standard? The schoolmaster seems now to have little pleasure in life, he is a mill-horse working round a pivot, a mill-wheel supplied with water to do one thing—namely, polish boys. Let the public see that they take care that those to whom they entrust the education of the medical practitioner are allowed some scope for their imagination, some opportunity to develop the individuality of their students. The essentially evil feature of centralisation is its want of personality. Our medical schools still possess some personality; it will be a bad day when that is interfered with. This school to which we happily belong, will lose much of its brightness, will be hampered in its usefulness, if its teachers are compelled to degenerate into polishing machines. May I ever have before me, as an important part of my duty, the encouragement of the individuality of my students. May I be enabled ever to remember that I am dealing with men, each one of whom has some special ability, every one of whom has some special work. May I endeavour, as far as in me lies, to search out that special ability, to encourage and to direct that special work. Give me your help in the future as you have always done in the past; without your confidence I can do little, with it I will endeavour, by devotion to my duties as your teacher, to maintain the reputation of this school for honest work. Working together, let us day by day feel that something has been attempted, something has been done, and at the end of the session we will be able to look back with an inward feeling that, while far from what it should have been, some advance has been made, some problem has been solved. Remember that to everyone present a talent has been given. Let him look to it that he uses that talent aright.

A FEVER-STRICKEN CREW. — Lloyd's agent at Norfolk, Va., telegraphs that the *Marie Anne*, French brig from St. Domingo to Havre, had been towed into Norfolk, Va., by the Spanish steamer *Bellver*, with only three men on board, all the others, including the captain, having died of yellow fever.

## ON THE ACTION OF THE SALTS OF SODIUM, AMMONIUM, AND POTASSIUM.

By SYDNEY RINGER, M.D.,

AND

HARRINGTON SAINSBURY, M.D.

THE difficulties attending the observation of the action of drugs clinically result obviously from the complexity of the phenomena presented; in like manner, the pharmacologist, so long as his investigations relate to the animal organism in its entirety, has essentially to deal with the complex. Inference under these circumstances is correspondingly difficult. If to avoid this source of error our observations be restricted to a portion of the organism, it is clear that our inferences gain in exactitude in exact proportion to the simplification effected. The difficulty now lies in the applicability of inferences so gained when we pass to conditions no longer simple. It was with this difficulty clearly in view that the experiments, the results of which will now be shortly discussed, were undertaken.

The ventricle of the frog's heart was the test tissue selected. Through such ventricle of a heart isolated from the body an artificial circulation was maintained, whilst by means of a suitable apparatus (Roy's tonometer) the contractions were registered on a revolving blackened cylinder. The particular drug used was added to the circulating fluid. We were thus able to compare the working of the drugged and undrugged ventricle under conditions, artificial it is true, but definite and under control.

The structure and function of the tissue so selected are essentially twofold: ganglionic structures and muscular fibres on the one side; rhythmic contractility on the other—i.e., rhythm and contractility. The nervous nature of rhythm may be debatable; but that contractility is muscular is certain.

On such rhythmically contracting heart the action of the salts of potassium, sodium, and ammonium is briefly as follows:—

All three arrest the ventricle in diastole; they contrast, however, in the mode of arrest. Thus, as to their action on rhythm: Potassium salts tend markedly to arrest or suspend the spontaneous contractions, whilst yet the heart may be proved to be contractile by suitable excitation. Ammonium salts show no such tendency; the heart beats, often with an increased frequency, up to the very end—i.e., as long as contractility persists. Sodium salts fit in between, but come very much nearer ammonium than potassium salts; their action on rhythm being very slight.

As to their action on contractility, we have, on the one hand, potassium and ammonium salts acting with almost equal intensity; on the other hand, a wide gap intervening, sodium salts showing but feeble action.

One other point of contrast may be mentioned, it refers to the effect of continuous faradisation. This rapidly loses its power to excite the ventricle to contraction when a potassium salt is used; not so for the other bases, and the very slight and somewhat inconstant effect for ammonium and sodium salts contrasts strongly with the uniform and marked effect of potassium salts.

Restricting ourselves to these broad lines of contrast, some important points come out:—

First, an important fact—namely, that throughout the salts of potassium, sodium, ammonium, the potassium, sodium, and ammonium elements are traceable. Indeed, in these experiments they appeared to rule the effect. (Quite recently, in a leading article, reference is made to experiments on unstripped muscular tissue by Nothnagel; the same result was observed here, the potassium and sodium action appearing to be independent of the combination of these bases. These experiments, then, on isolated tissues would be confirmatory of the older statement by Guttman with reference to potassium salts—namely, that they are all exactly alike in the character and intensity of their action.<sup>1</sup> The results, however,

<sup>1</sup> For further details consult papers by the authors in the *Medico-Chirurgical Transactions* (vol. lxxv.), and in the *Practitioner* (Aug. 1882).

<sup>2</sup> THE LANCET, July, 1882.

<sup>3</sup> Wood's Therapeutics, third edition, p. 484.

probably represent but a partial truth. The completer statement probably should be that elements and groups of elements retain more or less of their individuality throughout their combinations, and this would surely apply to either side of a salt—the base and the acid. The value of such statement would be as a help towards classification.

Next, that under these simple conditions specified, a certain relation between potassium, sodium, and ammonium salts is manifest. Potassium standing first as most poisonous and threatening in two directions; ammonium coming next, its action being restricted to destruction of contractility; sodium coming last and ranking as but very slightly poisonous comparatively with either. These experiments, indeed, would make potassium salts some fourteen or fifteen times as poisonous as sodium salts. Is the conclusion not warranted that in their action on the muscular tissue of the ventricle, and on its intrinsic nervous apparatus, these salts will maintain a *like* relation, even though the conditions be the more complex and indefinite ones of the organism in its entirety? It is not that one would exclude action on the nerve centres, *vagus*, &c., from the effect witnessed on the entire organism, but that one would specify *one* from among the many factors in the equation. This relation of the salts of potassium, sodium, and ammonium has however been tested on other tissues, and found to hold—e.g., on the nervous system.<sup>4</sup> The results also with the entire organism show that whilst potassium salts are very poisonous, sodium salts can scarcely be made to kill.

Insistence has already been made in various quarters on the use of sodium and ammonium salts in preference to potassium salts; more especially has this been urged for the bromides.<sup>5</sup> (The bromide of sodium has been rather largely used in America.) Clinical evidence must obviously give the final judgment; but have we not here clear indication as to the lines on which clinical investigation should be pursued?—the suggestion being that salts of sodium should throughout be substituted for those of potassium and ammonium, till clinical evidence decide that the action of one or other of these bases is required in the particular case under treatment? This suggestion, then, is based not only on the results of experiments with the entire organism, but also on these more definite results gained from experiments on isolated tissues.

It may be added that both at the Children's Hospital, Great Ormond-street, through the kindness of Dr. Barlow, and at the Western General Dispensary, Marylebone, we have had the opportunity of trying the chlorate of sodium<sup>6</sup> in cases of stomatitis, with ulceration along the edges of the gums, but few cases up to the present have been collected. So far, however, the evidence in its favour is every bit as unequivocal as it is for potassium chlorate, which might be said to be one of the show drugs in therapeutics. Two of the cases gave the best kind of evidence obtainable; they were, namely, cases of relapse, and were cured by pushing the drug.

## NOTE ON THE CLINICAL CHARACTERS OF TUBERCLE IN BONE.

BY WM. SCOVELL SAVORY, F.R.S.,

SURGEON TO ST. BARTHOLOMEW'S HOSPITAL.

It is curious on reflection to see how many striking points of analogy there are between the progress and effects of tubercle in lung and in bone. In the first place the cancellous texture of bone, which is the seat of tubercle, resembles broadly in physical characters the parenchyma of lung. A section of cancellous bone and a section of dried lung have to the naked eye a very general resemblance. The structure of both is aptly described as sponge-like, and this resemblance is drawn more closely when a mass of yellow tubercle occupies the substance of each. In both cases the

spongy texture appears to be filled up and rendered solid by the infiltration of the caseous deposit. Then, too, the resemblance further appears in the halo of inflammation or increased vascularity of varying width which so often surrounds the mass. Still further is the likeness shown in the mode in which the tubercle degenerates. The included tissue is broken down and destroyed until, either by the escape or disappearance of the tubercle, a cavity is left in the cancellous bone corresponding very remarkably to a vomica in the lung. Furthermore, the likeness is extended by the relation of cancellous bone to a neighbouring joint and the relation of lung substance to the pleura. Just as pleurisy is so often set up by the disturbance of tubercle in the lung, so synovitis is often provoked by the disturbance of tubercle in adjacent bone; and just as empyema is sometimes produced by the perforation of the lung-wall and the escape of matter into the pleural cavity, so suppuration in a joint, which is too often destructive, is due to the perforation of the articular wall of bone and the escape of matter into the synovial cavity. In either case urgent symptoms are apt to supervene suddenly on comparatively latent mischief.

Then, I think, the variable progress and effect of tubercle in the lung are oftentimes repeated with singular resemblance in bone. This first struck me many years ago in studying the graphic picture which Dr. Latham drew of the various forms of phthisis in his masterly Lectures on Clinical Medicine, which, by the way, have been happily reproduced by the Sydenham Society under the editorship of Dr. Martin. Just as in lung, so in bone; the history of tubercle is sometimes that of a single formation, which passes steadily, with more or less rapidity, to destruction; sometimes that of several smaller ones simultaneously; sometimes, though this more rarely, that of a number of successive formations which pass through their stages one after another, leading in this way to a gradually extending destruction of osseous tissue. So, again, and in this I think the resemblance is most marked of all, there are in tubercle in bone phenomena very exactly corresponding to what Dr. Latham in the lung, and in the cervical glands as a more obvious illustration, has described as cases of mixed and unmixed phthisis. In one class, during the changes which tubercle, after its formation, is prone to undergo, there is only what may be called a necessary amount of inflammation excited in the surrounding texture, such as is just sufficient to accomplish the result of softening and expulsion, and which subsides as soon as that is effected. This Dr. Latham called the specific limit of the disease. In another class the inflammation provoked spreads widely and deeply beyond this, and becomes much more severe and extensive than is needful for the mere elimination of the tuberculous matter. In short, Dr. Latham's sketch might have been drawn from a study of tubercle in the head of the femur or tibia or in the tarsus or vertebra.

Within the whole range of pathology I know no better illustration of the value of extended study, or rather of the great loss from limited views which must come of too special observation. For the study of tubercle, if the difficulty would be adequately grasped, must be carried on not only throughout the whole fields of medicine and of surgery, but here, at all events, there can and ought to be no boundary between them. For the largest purpose, the land to be explored must be common to both.

Brook-street, W.

## ANOTHER NEW TEST FOR ALBUMEN.

BY GEORGE JOHNSON, M.D., F.R.S.,

PROFESSOR OF CLINICAL MEDICINE AND SENIOR PHYSICIAN TO KING'S COLLEGE HOSPITAL.

My son, G. Stillmest Johnson, in a paper published in the *Journal of the Chemical Society* (August, 1874) describes some compounds of albumen with the mineral acids, and gives a table showing the action of various chemical reagents in causing coagulation in solutions of these albumen compounds. He found that only two reagents besides the mineral acids cause the coagulation of albumen in solutions of all its acid compounds—namely, baric chloride and picric acid,—and he suggested to me that the latter of these two substances might be found a useful test for albumen in the urine; for while the baric chloride could not be added to normal urine without being precipitated by many of its

<sup>4</sup> Ringer and Murrell: *Journal of Anatomy*, vol. xii., p. 71. For further reference see also Wood's *Therapeutics*; articles Potassium Salts; also *Phys. Action of Sodium and Ammonium Bromides*. Third edition, 1881.

<sup>5</sup> See Wood's *Therapeutics*, Bromide of Sodium. Also paper on *Epilepsy with Cardio-Complications*, by W. A. Hollis, M.D., *Practitioner*, vol. xxii., p. 81.

<sup>6</sup> Through the kindness of Mr. Martindale we were provided with a pure specimen of this salt.

normal constituents—sulphates, carbonates, and phosphates—picric acid causes no precipitate in normal urine.

Acting upon my son's suggestion, I have for some months used a saturated solution of picric acid as a test for albuminous urine, with results which may be briefly stated as follows: In normal urine it has never given a precipitate or produced any other change than the slight yellow tinge due to the colour of the solution, the mixture remaining quite transparent. When heat and nitric acid, applied with the usual well-known precautions, have shown the presence of albumen, the picric acid solution has invariably caused coagulation in proportion to the amount of albumen.

Most clinical observers are agreed that one of the most delicate tests for a minute quantity of albumen consists in the addition of nitric acid to the cold urine, when a cloud appears at the junction of the two liquids. In applying this test the urine may be poured upon the acid which has been previously placed in the test tube, or the urine having been poured into the test tube, a few drops of the acid are allowed to flow down the side of the tube while held in a sloping position. It sometimes happens that when the amount of albumen is very small an interval of some minutes elapses before any change occurs at the junction of the two liquids. Now, in such cases I have found that a mixture of equal volumes of the urine and the picric acid solution has immediately become turbid with coagulated albumen. In this speedy and decided action of the test upon urine which is only slightly impregnated with albumen, the picric acid solution is superior to nitric acid. In applying this test it should be borne in mind that the picric acid saturated solution is but little heavier than distilled water, its specific gravity being about 1003; so that, unlike the heavy nitric acid, it tends when slowly poured into the tube to float on the surface of the urine, where a film of coagulated albumen forms at the junction of the two liquids. This floating film with the picric acid solution forms a pretty contrast with the film near the bottom of the test tube when nitric acid is the reagent employed. The coagulum formed with the picric acid solution in cold urine requires a very large excess of water for its solution; in fact it is about as insoluble as the coagulum produced by nitric acid. The picric acid coagulum is readily soluble in caustic potash and ammonia; if, therefore, albuminous urine be alkaline it will require to be neutralised or acidulated before applying the picric acid test; but in all my numerous testings with the picric acid I have not once found it necessary to acidulate the urine. One result, then, of my industrious son's purely scientific work at these compounds of albumen has been to supply us with a really valuable addition to our tests for albumen in the urine.

Then it has lately occurred to me, what is obvious enough when once attention is directed to it, that for a saturated solution of picric acid the crystals or the powder may sometimes be substituted with advantage. A small crystal added to the albuminous urine quickly dissolves and as quickly coagulates the albumen. The crystals are permanent in the air, and may be kept for any length of time without undergoing change; and I venture to predict that a few of these crystals in a small bottle will speedily take the place of nitric acid, whether in sealed tubes or in bottles, in all urinary test cases which are made for carrying in the pocket. With picric acid powder or crystals in one bottle, and Cooper and Fehling's test pellets in another, the most complete urinary test case need contain no other liquid than the spirit in a small tubular spirit lamp. I have for some years carried in my case nitric acid in a well-stoppered and capped bottle, and then enclosed in a boxwood box; but I now with a sense of relief replace the destructive liquid acid for the entirely harmless solid.

Since the preceding was written I have met with two specimens of urine suspected to be albuminous, in which picric acid caused a decided opalescence, while nitric acid only darkened the colour of the urine. I am therefore confident that in some cases picric acid will prove to be a more delicate test for a mere trace of albumen than nitric acid. In the solid form the powdered picric acid has this advantage over the crystals, that it dissolves more rapidly.

Savile-row, W.

DR. SEDGWICK SAUNDERS, the Medical Officer of Health for the City, in his report last week, stated that of 302 houses, thirteen required sanitary improvement.

DR. J. C. NUNAN has been elected chairman of the Kinsale Town Commissioners.

## RUPTURE OF THE URINARY BLADDER.

By WALTER RIVINGTON, F.R.C.S. ENG.,  
SURGEON TO THE LONDON HOSPITAL.

### PART III.

#### REPORTED CASES OF RECOVERY AND TREATMENT.

THE reported cases of recovery after rupture of the urinary bladder with which I am acquainted are twenty-six in number, and may be arranged as follows:—

1. Partial or subperitoneal ruptures. One case under Mr. Keal.

2. Extra-peritoneal ruptures. (a) Rupture into the vagina. Three cases under Wilkinson, Earle,<sup>1</sup> and a friend of Dr. Blundell's<sup>2</sup> respectively. (b) Rupture into the rectum. Two cases under Ward<sup>3</sup> and Call<sup>4</sup> respectively. (c) Perforations by splinters of bone. Four cases under Astier, Eve, Townsend, and Thompson respectively, to be found in Dr. Max Bartels' paper. (d) Ruptures into the perivesical connective tissue. Eight cases under Syme,<sup>5</sup> Porter,<sup>6</sup> Walker,<sup>7</sup> Padley,<sup>8</sup> Rose,<sup>9</sup> Max Bartels,<sup>10</sup> Berner,<sup>11</sup> and Jeanmaire<sup>12</sup> respectively; and to these I might add a case which came under my own observation.

3. Intra-peritoneal ruptures. Eight cases reported respectively by Walter,<sup>13</sup> Le Gros Clark,<sup>14</sup> Erskine Mason,<sup>15</sup> Thorp,<sup>16</sup> McDougall<sup>17</sup> (two cases), Morris,<sup>18</sup> and Chaldecott.<sup>19</sup>

Partial or subperitoneal ruptures may be more common than is generally supposed, and Mr. Keal's case requires no comment.

In the examples of rupture into the vagina, distended and neglected bladders gave way in consequence of the accession of labour and the use of instruments. The rents were in a most favourable situation, and in this class of cases there is nothing to militate against recovery.

Of the rectal cases, one (Ward's) was secondary from sloughing, and the other (Call's) appears to me to have been probably a rupture of the membranous urethra into the rectum. Such communications are sometimes met with in cases of stricture.

The cases of perforation of the bladder by fragments of bone are only included because they appear in Max Bartels' list. Splinters from fractures of the pelvis pierced the bladder. In one case a splinter came from the urethra; in the others the splinters became encrusted with phosphates, and were removed by lithotomy after the lapse of months or years.

Six of the extra-peritoneal ruptures (Syme, Porter, Rose, Max Bartels, Berner, and Jeanmaire) are undoubtedly genuine instances of recovery after traumatic effusion of urine into the perivesical connective tissue, and require no comment. Mr. Padley's case was not traumatic. The patient had a tight stricture, and urine appears to have escaped from the bladder in consequence of a syphilitic ulcer perforating the wall of the viscus. Of the genuineness of Dr. Walker's case I am far from convinced, and the second-hand report of the case to which I have alone had access is so brief that I reserve a final judgment. A man, twenty-three years of age, had been crushed between an engine and a car. His bladder is said to have been distended. A tumour appeared anteriorly, which subsided when the catheter was used. A rupture of the anterior wall of the bladder was diagnosed, and lateral cystotomy was performed with subsidence of the freshly accumulated tumour, and tenderness. Improvement and rapid convalescence followed, and in fifty-five days the patient resumed his occupation. In the absence of clear

evidence that the bladder was distended at the time of the accident this case is open to grave doubt. If urine had escaped from the bladder into the perivesical connective tissue, immunity from suppuration and sloughing could not be expected, nor could lateral cystotomy have removed the collection of urine. The fact that both catheterism and lateral cystotomy removed the tumour is a strong argument in favour of that tumour having been really caused by the bladder itself.

My own case was that of a woman, twenty-three years of age, who came under my care at the London Hospital for supposed hip disease. Eighteen months previously she had fallen down whilst pregnant, and three weeks after the accident she gave birth to a dead foetus seven months and a half old. Parturition was favourable, but she was ill directly afterwards, and suffered from a constant pain in the side. Suddenly the pain removed to the right groin, and abscesses formed, leaving discharging sinuses. One day urine was found issuing from these sinuses by my dresser, Mr. Needham. Ultimately, after she had left the hospital, she made a complete recovery, and has since borne children.

Out of the eight cases of reported recovery after intra-peritoneal rupture, abstracts of six will be found in Max Bartels' list—viz., those reported by Walter, Erskine Mason, Thorp, McDougall (2), and Chaldecott, and only one (Walter's) is admitted by that laborious and careful author as a genuine case of recovery after intra-peritoneal rupture. He disposes of four—viz., the cases of Thorp, Erskine Mason, and McDougall—by regarding them either as errors of observation or as cases of subperitoneal or extra-peritoneal rupture mistaken for intra-peritoneal. Chaldecott's case is passed over in silence. Dr. Walter's patient was a man aged twenty-six, who had received a blow on the lower part of the belly. Abdominal section was performed ten hours after the accident. A sponge introduced mopped up nearly a pint of urine and extravasated blood. A rent was observed in the base (?) of the bladder, two inches long. This rent was left to itself. That the foregoing is a genuine case of recovery can scarcely be questioned, unless it is possible for an observer to mistake serous fluid and blood for urine and blood, and by an optical illusion to fancy that he sees a rent where none exists. Mr. Heath demonstrated the rupture in his case by passing a catheter into the bladder and through the rent, and it would have been as well if some precaution of the kind had been adopted by Dr. Walter, so as to leave no room for scepticism. As to Thorp's case has been elevated into a fiction, and changed by the imprimatur of Mr. Heath. The patient, a man, thirty years of age, who was thrown from a horse whilst intoxicated, and was found lying by the roadside. Dr. Thorp made the diagnosis, before he had introduced the catheter, from the bent posture of the patient, the rigidity of the abdominal muscles, and the urgent and constant desire to pass water; and the diagnosis was "placed beyond the possibility of doubt" by the empty state of the bladder and the change in the direction of the catheter. The most expedient means to obtain urine. No examination of the bladder at the time of the accident was obtained, and several prominent symptoms were absent. Dr. Thorp's treatment was what he considered to be the best, and the peritoneal cavity by means of a catheter was washed with an indiarubber bag. Tepid water, to the amount of three gallons, was injected through the instrument, and a bagful of about eight ounces was injected, and the same quantity removed, showing positively and finally that the fluid had indeed entered the circumferential cavity of the unruptured bladder.

In neither of Dr. McDougall's cases is there any satisfactory evidence of distension of the bladder at the time of the accident, and some of the most characteristic primary symptoms of rupture were conspicuously absent. Few surgeons would have any hesitation in setting aside the first case related. The second case rests mainly on the inability to micturate, the presence of blood in the urine, the small quantity of urine drawn off by the catheter, and the removal after an interval of a few hours of twenty-one ounces of fluid by means of the aspirator. Dr. Max Bartels carefully excludes the case from the category of intra-peritoneal ruptures, but seems willing to admit that it may have been an extra-peritoneal rupture; but even this view is attended with difficulties, to my mind insuperable. I believe that there was some unusual condition interfering with the withdrawal of the urine by the catheter, and that the aspirator entered the bladder itself. Dr. Erskine Mason's case has been freely criticised by Mr. Willett, who had no difficulty in rejecting it as an

intra-peritoneal rupture, although he concedes an extra-peritoneal rent, and allows Dr. Mason the credit of having saved the life of the patient by lateral cystotomy. Curiously enough, Mr. Willett did not see that the absence of evidence of a distended bladder, and of direct injury to the hypogastric region, as well as the other details of the case, militate equally against an extra-peritoneal rent behind the prostate; and, as I read the case, Dr. Mason himself proved by digital examination that there was no effusion of urine between the rectum and prostate or anteriorly to the latter organ, and inasmuch as a collection of urine in a cavity behind the prostate and on the left side would not have been reached by a lateral lithotomy performed like Dr. Erskine Mason's operation *secundum artem*, by a limited incision, and inasmuch as bloody urine escaped in quantity when the apex of the prostate was only notched, before the finger even was introduced, it follows that the fluctuating tumour felt behind the prostate was the bladder itself, and that the catheter had never fairly reached the urine collected in the vicus.

Mr. Morris's case reads to me like one of severe contusion of the abdomen of the pelvic fascia and peritoneum, and of the bladder itself. The evidence of distension of the bladder is defective, as the man had passed water about an hour before the injury. According to the patient himself, he passed by his own efforts three-quarters of a pint of urine in the first thirty-six hours, and very likely the quantity was greater. On admission to the hospital the catheter removed three or four ounces of clear urine, and failed to detect any rent in the bladder, although moved about for the purpose. Plenty of urine was drawn off daily through an elastic catheter fixed in the bladder.

In Mr. Chaldecott's celebrated case it is a most unfortunate circumstance that no evidence is adduced to prove the fullness of the bladder at the time the patient ran against a post, beyond the mere fact that the patient himself felt a strong desire to make water, and hastily crossed the road for the purpose. To describe the bladder as full or distended on this evidence is a *petitio principii*. We are asked to believe that urine was poured into the peritoneal cavity, and was rapidly absorbed, taking in a few days the form of gout; that peritonitis at the same time was set up, and began to subside in twenty-two hours after the accident, on the administration of two scruples of sedative solution of opium. It is true that Mr. Aston Key saw the patient, and thought that the bladder was ruptured; but Mr. Aston Key did nothing to demonstrate the rent by passing the catheter into the peritoneal cavity, through the rent in the bladder. Is it not far more probable that the case was really one of suppression of urine complicated with the effects of the accident, due to latent gout, and passing off under warmth and opium, than that the bladder was ruptured, and that urine poured into the peritoneal cavity was rapidly absorbed and converted into gout? I cannot see that the difficulties of the case are diminished in the least by regarding it as one of sub-peritoneal, or extra-peritoneal rupture, and the theory of suppression has not yet been disposed of satisfactorily.<sup>20</sup>

(To be concluded.)

## CASE OF CYSTIC BRONCHOCELE.

IMPENDING ASPHYXIA; ASPIRATION; RELIEF; EARLY RE-ENLARGEMENT; ATTEMPT AT RADICAL CURE; TRAUMATIC FEVER; DEATH.

By HERBERT A. SMITH, M.R.C.S., L.R.C.P. ED.

IN common with many localities in which goitre is especially endemic, North Wiltshire might be included in the list of districts where the disease is very prevalent. The chalky character of the soil and the glaring white appearance of the hilly "cuttings" are particularly noteworthy to the stranger; the permeation of watercourses through these, and their impregnation with lime salts, are therefore but natural phenomena. Malarial diseases proper are, however, rare, and thus goitre, deprived of a malarial element, is

<sup>20</sup> Dr. Eben. Watson advanced the view of suppression in the Edinburgh Monthly Journal, Oct. 1848 and 1849, p. 561. A controversy took place between him and Dr. Gillespie in the Edinburgh Medical Journal, March, 1850, p. 811, and the Glasgow Medical Journal, 1850. Dr. Gillespie combated Dr. Watson's arguments with some success, but the theory of suppression was by no means disproved.

generally an innocent and slow-growing formation. Two views might be advanced respecting the pathology of the cystic variety: (1) that the lining membrane of the vesicles of the thyroid gland proper, already enlarged by the same agency, has a special affinity for the lime salts, and, appropriating them, undergoes progressive development, and so general coalescence; or (2) that the elaborate vascular supply of the gland finds in these vesicles a harbour of refuge for the superfluous salts of the blood, which effect their hypertrophy. We find that water-drinkers—e.g., women and teetotallers—mostly suffer from the disease, and that change of locality and habits of life are alone fruitful in staying its further development. The stationary character of the disease already developed, without the local exciting cause, certainly supports this view. Conversely, I find that rickets is an almost unknown disease in this locality.

S. C.—, aged fifty-five, a well-developed, temperate, somewhat stout woman, of anæmic appearance, who has generally had good health, the mother of sixteen children, was born and has always lived at her present home (Mere). She states that she first noticed a fulness in her neck after the birth of her last child (sixteen years ago), and that gradually enlarging the right became larger than the left side, and that proportionate development of each lobe continued until recently. Semi-spherical in shape, the left lobe partakes of a prominent globular form in front. Each is smooth, elastic, tense, and fluctuating, the gland as a whole being non-adherent above and below. The transverse measurement of both lobes is  $11\frac{1}{2}$  in., the vertical measurement of the right lobe being  $5\frac{1}{2}$  in., that of the left  $5\frac{1}{2}$  in. The lateral boundary of the right is one inch beyond the outer edge of the sterno-mastoid muscle, that of the left half an inch beyond the outline of the fellow muscle, the inner boundary of the same lobe slightly encroaches on the right side, obscuring above the pomum Adami (prominence) the gland extends inferiorly half an inch below the sternal notch; the outline of the right lobe is regular, the surface of each mottled with prominent veins and dilated capillaries; no tenderness or redness; there has been an absence of reflex symptoms, save when she has had "a cold." Deglutition has been hitherto painless (ordinary diet), utterance thick, dyspnoea urgent only in the recumbent position, when compression of the two lobes greatly lessens her breathing power; exertion, excitement, and lying down have, since her last bronchial attack, however, caused urgent dyspnoea, dysphagia, and a noisy stridor is manifest in her respiration and speech; the expression, moreover, is anxious and pallid. Compression of the gland below is slight, the lower portion being supra-sternal. She has sought advice from many medical men, chemists, and, lastly, homœopaths, who equally rung the changes between paints, unguents, and specifics, externally and internally, but all of no avail in the appreciable reduction of the tumour. A few days after consulting me she had symptoms of impending asphyxia, from a bronchial catarrh superadded to a compressed trachea; dyspnoea was extreme, respiration feeble and rapid, face livid and extremely anxious. There was every indication for surgical relief. Finding the growth cystic and fluctuation distinct, I decided on aspiration on the left side, using the largest trocar. This done, a dark coffee-coloured partly flocculent, partly ropy-looking fluid mixed with a brickdust sediment came with a rush into the bottle, in all seven ounces and a half, when, relief being obtained, the trocar (already blocked) was withdrawn, as the patient showed signs of syncope, and the further evacuation of the cyst (which the trocar freely explored) was left for a second sitting. On examining the fluid it was found highly albuminous (one-third), inodorous and alkaline, sediment in colour, consistence, and character like liquid tomato sauce, holding in suspension white shining lenticular pseudo-crystals of varying size; these were probably the broken down debris of the concretions (arranged in strata) of the lining membrane.

May 14th: Wound of puncture healed. Passed a good night, sleeping five hours; some tenderness. Tumour rapidly gaining its original size. The bandage (to support intracystic vessels) to be loosened. Ordered a stimulant draught every four hours. Deglutition followed by movement of the left lobe upwards and to the left; the same lobe bulges half an inch beyond the middle line; general condition good; little local discomfort.—19th: Pain during speech and deglutition in the right side, mostly over the large vessels. Nerve irritation over the upper border of left lobe (intra-cystic distension); "feels dazed often, and I has

visions of foreign bodies, with dragging of the cords of the eye." Aconite liniment was applied.—20th: One week after date the measurements were—transverse measurement of gland,  $10\frac{1}{2}$  in.; vertical measurement of right lobe,  $6\frac{1}{2}$  in.; vertical measurement of left lobe,  $6\frac{1}{2}$  in.—24th: Some pain, and stridor, which is noisy; speech thick. There is now bilateral fluctuation. General health good.—27th: Having suspected more fluid remaining at last aspiration, and tumour having refilled, I decided, with full wish of patient, to repeat the process, and during this sitting removed fourteen ounces of fluid, thinner and brighter (sediment one-fourth), reducing the neck to nearly its normal dimensions. Although the patient bore this well, and support to the neck was given, the following day the measurements were: Transverse measurement of gland, 9 in.; vertical measurement of each lobe,  $4\frac{1}{2}$  in.; circumference of neck, 20 in. No subsequent bad symptoms supervened, but refilling of cyst is manifest again.

June 17th: Urgency again marked from re-enlargement of gland, noisy stridor, dyspnoea, lividity, and anxiety of

The dotted line records the temperature without salicylate treatment. The thick line shows the body-heat during the employment of that treatment.

countenance. Measurements: Transverse,  $9\frac{1}{2}$  in.; vertical of right lobe,  $6\frac{1}{2}$  in.; vertical of left lobe,  $6\frac{1}{2}$  in. At the patient's wish that something "more lasting" might be done, with the idea, as suggested by Dr. M. Mackenzie (Clin. Soc. Trans., vol. ii., page 15) of destroying the secreting power of the lining membrane and promoting suppuration, I offered and performed paracentesis, subsequently injecting the cavity (through the cannula) with a solution of iron tincture (two drachms to the ounce); of this, one drachm was retained after evacuation, which gave thirteen ounces and a half of dark, bloody serum. Prior to injection it was found necessary to free the cannula as it became blocked. The probe exploring fully eight inches of the monocyst transversely, it gave no pain. Antiseptics were not used, but

all instruments after cleansing thoroughly were steeped the previous night in a carbolic solution (one in forty). After injection the cannula was retained *in situ*, and plugged with carbolised tow, and a support to the collapsed tumour given by strapping (broad strips) placed transversely half-way across the neck.—18th: Temperature 99.4°; respiration 24; pulse 84. She is languid, feverish, and complains of constriction of the strapping; on being loosened, instant relief followed, although anterior bulging of the tumour (now tender) shows that inflammatory swelling has set in. Support by means of a soft handkerchief and a stimulating draught ordered, also a compound senna draught. The same evening a rigor, followed by sweating, occurred. Temperature 102°; respiration 36; pulse 120; effusion, pain, and swelling increasing.—19th: Temperature 103°; respiration 36; pulse 120. To have compound citrate of potash draught, and diffusible stimulants.—20th: Temperature 104°; respiration 44; pulse 132. Early rigor (6.30 A.M.); pulse small; tongue foul; face flushed; skin hot, pungent; conscious. Ordered fifteen grains of salicylic acid every two hours; removal of cannula, substitution of a rubber drainage-tube, and a poultice to bring on early suppuration. Evening temperature 99.2°; respiration 24; pulse 116; free sweating (clammy); respiration tranquil; face still flushed; escape of fetid fluid from the drainage-tube; neck suppurating.—21st: Rigor (6.45 A.M.); temperature 99.8°; respiration 24; pulse 120; bowels open twice. To continue the salicylic draught every four hours, and to take champagne.—Evening temperature 99°; respiration 20; pulse 104. Escape of half a teacupful of fetid serum and relief; face still flushed; clammy sweat. To anticipate rigor to take a full dose of salicylic draught in the morning.—22nd: Temperature 100.4°; respiration 30; pulse 104, full, regular. Complaints of noises in the head (draught) and cramps in the leg; conscious; no rigor. Evening temperature 101°; respiration 30; pulse 112. Semi-conscious; discharge from neck, though less; tongue foul; has gastro-umbilical pain (solar plexus). To have an enema.—23rd: Temperature 105°; respiration 32; pulse 132. Sighing, high-pitched respiration; muttering, restless delirium since early morning; *alae nasi* working; pallor of face; extremities cold, left leg especially, but dorsalis pedis found pulsating; pupils contracted, insensible. Some rhonchus on the right side; tumour tense, much enlarged, pungently hot, and dusky; office of wound choked with coagulum; right lobe refilled and fluctuating; left lobe tense, tender, and fluctuating in upper, dull and solid in the lower, meridian. Treatment: Removal of clots; renewal of fomentation; to continue salicylic draught and champagne; hot bottles to the feet. 4 P.M.: Continuation of delirium. Death from coma. Shortly after death the cyst ruptured, discharging per ora half a pint of fetid pus; tumour extending from chin to sternum; gangrenous. No post-mortem allowed.

*Remarks.*—The coma was induced by the compression of the large cervical vessels, the previously high temperature being unattended with unconsciousness. A rigor thirty-one hours after the operation foretold the onset of the traumatic state; the departure of the temperature, of which a chart is annexed, from the normal is explained by the salicylate treatment, which brought it down five degrees on the third day; the morning rise on the fifth was recorded after a rigor; of these three were marked, and a fourth (unnoticed) preceded the rise to 105° in my opinion. The mechanism of effusion in this case was interesting. Twenty-four hours after the operation by either method the tumour had enlarged to within 1½ in. of the transverse and 1 in. of the vertical measurement, giving roughly an average of half an ounce secreted per hour, not allowing for that absorbed; after this, compression of effused contents allowed but little if any further secretion. The early enlargement of the cyst is due evidently to the power of effusion the lining membrane possesses, its stationary character to the process of absorption in the absence of a serous membrane being at zero. Had the one kept pace with the other, putrefaction would not have occurred; there would have been a limit to the tension. The question now arises, Did the cause of the high inflammatory action set up rest in the introduction from without of invisible germs that rendered the fluid infective? It is admitted that the exudation of serum is not infective as alike are organisms without; could then a chemical change in the exudation products leading to genuine suppuration take place as readily with antiseptics as without? Could it occur at all without the presence of micro-organisms? Occurring in an isolated country cottage,

a model of cleanliness, it would seem that there was not sufficient chance of the air containing septic matter even in a diffused form to prove effective in blood serum to make it necessary to raise the question at all. Again, if as an irritant the injection of iron, as in rodents (Wegner), is always infective, and the exudation products are thereby septic, and if the aim of our treatment, suppuration, is invariably attended with the presence of septic organisms, it seems to me that antiseptics are not indicated; if, on the other hand, the inflammatory changes that accompany the use of antiseptics are of limited extent and duration (Sanderson), our course is obvious. Yet my treatment is counselled by a great authority. The presence of septic organisms generated from without in common with the bacilli of tubercle (Baumgarten) must first be proved by some well-known and simple test before the danger signal is upheld against our surgical resources divested of an antiseptic element; if, on the other hand, we are to be guided by Professor Hueter, we must invariably use antiseptics in our practice, taking our sprays suspended to our pack-saddles, even into remote country districts, in carrying out the theory that "organisms exist everywhere, ready, whenever access is offered to them, to enter the body and to fulfil their morbid function."

Ealing.

## SUCCESSFUL EXTIRPATION OF THE LARYNX.

By WALTER WHITEHEAD, F.R.C.S.E., F.R.S. EDIN.,  
SURGEON TO THE MANCHESTER ROYAL INFIRMARY.

LARYNGEAL SURGERY has of late attracted considerable attention, and as the profession is somewhat divided in opinion on the respective merits of extra- and intra-laryngeal operations in dealing with laryngeal growths, I wish to place on record the particulars of a case favourable to the former procedure.

W. G—, aged forty-six, blacksmith, was admitted into the Manchester Royal Infirmary on April 28th, 1882, on the recommendation of a medical friend, who suggested the desirability of removing a growth which he had discovered attached to the right vocal cord. The patient had suffered from extreme hoarseness, difficulty in breathing, distressing cough, and occasional paroxysms of dyspnoea, for three months before coming under observation. Laryngoscopic examination afforded a conjectural diagnosis that the growth, which overspread the right vocal cord, was of an epitheliomatous nature. The disease could only be inferred to extend beyond the range of vision by the knowledge that malignant neoplasms in that locality usually extend below the cords. Tracheotomy was performed as a preliminary measure on April 30th, the operation giving immediate, but only temporary, relief to the more pressing symptoms. A recurrence of ominous dyspnoea, which was afterwards discovered to have been produced by the imperfect manner in which the cannula had been reintroduced after having been removed for cleaning, hastened the decision to remove the disease.

On May 27th the thyroid cartilage was slit from below upwards, and the two halves held apart, when it was seen that the new formation not only implicated the vocal cord, but extended, as was conjectured, downwards, and involved the upper part of the trachea. Before proceeding to excise the diseased structures, Trendelenburg's tampon was substituted for the tracheotomy cannula, and the insufficient protective influence of the tampon against blood finding its way down the air-passages was guarded against by packing the trachea above with a small sponge. The whole of the disease, the thyroid and cricoid cartilages, and the two upper rings of the trachea, were then removed by means of scissors. The epiglottis was left intact. The skin was brought together by a few silk sutures, and the wound dressed with dry lint.

On the following day Trendelenburg's tampon was replaced by a soft rubber tube which still remains *in situ*. A microscopic examination of the growth confirmed the diagnosis as to its being an epithelioma. The patient's voice was not immediately lost; for several weeks after the operation he could express himself in monotone and could be distinctly heard at a distance of six feet; gradually the sound faded and eventually disappeared altogether. It can still be demonstrated, by means of a flame in front of the mouth,

that air finds a channel in the track of the original air passages. The patient now breathes quite freely, takes his food without inconvenience, and enjoys life as fairly as can be expected under the circumstances. The absence of any local glandular enlargement or evidence of any recurrence of the disease affords a reasonable prospect that the patient may derive prolonged benefit from the operation. The idea of introducing the artificial vocal apparatus of either Gussenbauer or Foulis was entertained, but abandoned on the grounds that no real advantage had yet been established in favour of these instruments. The preference for thyrotomy was based on the opportunity it affords for a complete inspection of the entire larynx, and the facility it gives for extending or restricting the extent of the operation to any limit necessitated by the amount of the disease. The only difficulty met with during the operation was the separation of the deeper attachments.

Manchester.

## CASE OF PARASITIC AFFECTION OF THE MOUSTACHE.

By GEORGE THIN, M.D.

THE following interesting case which occurred in my practice is worthy of record for several reasons.

In April, 1876, a gentleman, aged about thirty, consulted me on account of loss of hair in one part of the moustache, a little to the right of the nose. He had recently returned from residence abroad, but was in good health, and very careful of his person. His strong black and handsome moustache was disfigured by a bald strip about a quarter of an inch broad, which passed from its upper to its lower border. The hairs on both sides of the bald strip were split at the ends, and were bent and withered-looking. On examining these altered hairs under the microscope, they were found to contain spores similar in size and appearance to those of *trichophyton tonsurans*. The disease of the hairs had

Hair from moustache affected with fungus growth (*confidia*), macerated in solution of potash, and mounted in glycerine. The dark part shows the portion of the hair in which the spores were present. Magnified five diameters.

existed, he told me, for five months. I directed him to brush his moustache twice daily with the following preparation:—Carbolic acid, one drachm; olive oil, two ounces and a half; lavender oil, six drops. In less than a month the disease had disappeared, and the bald part became again covered with healthy hairs. But the singular part of the history is to come. The disease was first observed in November, 1875. It reappeared in November, 1876, and every succeeding November until 1880 inclusive. Last November, for the first time since it commenced, it did not reappear. During the successive outbreaks the nature of the disease was verified by microscopic observation. In the attacks subsequent to the first the carbolic oil was used four times stronger than I originally prescribed it, and always with the speedy cessation of the loss of hair. The skin from which the hairs fell off remained healthy in appearance, showing no redness or scaling, or any signs characteristic of *tinea circinata* or *tonsurans* or of parasitic *tycosis*.

The two points that have led me to consider the case as remarkable are, first, the position of the fungus in the hair;

and, secondly, the reappearance of the disease in November for five successive years. In regard to the position of the fungus, the direction of the growth is different from that which I have observed in *tinea tonsurans*. In that disease the fungus grows into the hair-follicle between the hair-shaft and the internal root sheath, enters the shaft near the papilla, and grows outwards in the centre of the shaft. In this case the fungus attacked the free extremity of the hair, and grew downwards towards the skin. This is shown in the accompanying woodcut, which represents a drawing of an affected hair slightly magnified. In the woodcut the dark end is the free extremity of the hair, and represents the portion of the shaft affected with the fungus. The tapering extremity of the dark band in the centre of the hair accurately represents the manner in which the growth is found penetrating the shaft. Why this disease should have recurred each successive November can only be guessed. We must, I imagine, assume that some spores remained from each year to the following year, and that in November they found the conditions of growth. The parts of the hairs in which they grew were completely removed from the fluids of the body. Did they find in November the conditions of temperature and moisture suitable to their growth? The patient during these years enjoyed good health, lived in London, and led an active professional life.

Queen Anne-street, W.

## A NEW INTRA-UTERINE STEM, COMBINED WITH AN INSTRUMENT FOR KEEPING SEPARATE THE LIPS OF THE CERVIX AFTER INCISION.

By J. BERESFORD RYLEY, M.D.

It will, I think, be admitted without question that dysmenorrhœa and its wide-spreading effects solicit the attention of the profession more frequently than all the other diseases of the uterus put together. Any new mechanism therefore that has for its object the further alleviation of a malady so distressing, on account of its physical, physiological, and psychological consequences, will, I feel sure, be received with that consideration which its importance deserves. The idea of making the cervix uteri the *point d'appui* or fulcrum for an intra-uterine stem,

instead of the vagina or a point outside the body as has hitherto been the case, had been present to my mind in an indefinite shape for a long time, and is only the extension of another which had for its object a contrivance for keeping separate the lips of the cervix after incision. Those who have been called upon to perform this operation and all who have written on the subject are aware and assert that a successful issue depends altogether upon the tedious after-treatment and is but little affected by the mode of operating. Dr. Atthill of Dublin, than whom no one has written more practically upon this point, says in his "Diseases of Women," "Passing the uterine sound daily for at least two or three weeks subsequent to the operation and at intervals for some time longer, I find to be usually sufficient to prevent the divided surfaces from uniting." If one will but pause for a moment to consider the almost unbearable distress to the patient and the humiliating tedium to the practitioner involved in such a proceeding, it will not be wondered at that so many should have pronounced this operation to be most unsatisfactory. I have examined the cervix uteri after operation by most of the well-known gynaecologists in London and elsewhere, and have usually found that after a time its canal and outlet had contracted back to their originally abnormal conditions, and that the history of the majority of the patients was that they had had more or less relief for a few months after operation, but that the pre-existing symptoms had returned as severely as ever. Again, those who have had any experience in the application of the various forms of uterine pessaries must very often have

felt extremely disappointed with their general results, and will, I think, agree with me that not one-tenth of the patients for whom they are used obtain any marked benefit therefrom. Intra-uterine pessaries undoubtedly give much better results, but their mechanism hitherto has been so complicated and imperfect as to render their introduction and retention both difficult and distressing. I hope, however, that the instruments that I now submit to the profession will be found to obviate all the difficulties and distresses that I have enumerated. Their mode of application is so easy and the principle on which they are based so simple, that a glance at the diagram will be sufficient to indicate this without any tedious details on my part. It may be objected that an intra-uterine stem as applied in this manner will not alter any abnormal axis of the uterus; but I do not think that this is a matter of any great consequence, because the chief objects, I think, to attain by this mode of treatment are to straighten the organ in question and keep its canal pervious. It also may be thought that the metal pins on which the instruments are based might set up irritation at the points of puncture and easily tear through the structures, but I can answer from experience that neither of these objections will be found to be realised in practice, and that they can be worn for months without inconvenience. I hope that those who, like myself, make a special study of the diseases of women will give these instruments, which are made for me by Messrs. Krohne and Sesemann of Duke-street, Manchester-square, a fair trial, and kindly acquaint me with the results of their experience.

Finsbury-square, E.C.

OF

## HOSPITAL PRACTICE, BRITISH AND FOREIGN.

*Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tam aliorum tum proprias collectas habere, et inter se comparare.*—MORAGANI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

### SEAMEN'S HOSPITAL, GREENWICH.

**RUPTURE OF LIVER; THROMBOSIS OF HEPATIC VEINS;  
EMBOLISM OF A BRANCH OF LEFT PULMONARY  
ARTERY; PLEURISY; DEATH; NECROPSY;  
REMARKS.**

(Under the care of Mr. G. H. MAKINS.)

THE following case came under Mr. Makins' care while doing duty for Mr. W. Johnson Smith.

On Sept. 30th, at 3.30 P.M., J. R.—, aged twenty-four, a labourer, while in a state of intoxication, was run over in the street by an empty cart, and taken at once to the hospital. The wheel, it was said, had passed over the abdomen.

On admission he was in a state of collapse, and could not be got to answer any question; the countenance and lips were extremely pallid, the pupils dilated, the extremities very cold, and the pulse almost imperceptible. He was put to bed, hot bottles were applied, and a hypodermic injection of brandy (twenty minims) was given. At 8 P.M. he was much improved in appearance, answered questions rationally, but in an excited manner; smelled strongly of spirits; lay on right side. He complained of great pain and tenderness in the epigastrium, but was able to turn in bed without much suffering; no abnormal abdominal dulness; had been sick twice since admission; respiration 30; abdominal wall moving freely; no sign of fractured ribs; temperature 97°; extremities still very cold; pulse 130, small, but quite perceptible. Hypodermic injection of one-third of a grain of morphia. The bowels were moved some time after admission. The patient had a quiet night, but slept little, and next morning he complained of much pain in the epigastrium. The abdomen was slightly swollen and tympanitic; no abnormal dulness in flanks; temperature 98.4°; skin still pale, and hands felt cold; pulse 150, small; respiration 32, chiefly thoracic, but abdominal wall still moved; tongue furred, but moist; no further vomiting. One teaspoonful of

brandy was given every half hour; milk diet; ice; one grain of opium pill was given, to be repeated in half-grain doses every four hours. At 8 P.M. the opium had relieved pain; still pallor; temperature 97°; hands very cold; pulse 150, very small; respiration 44, entirely thoracic and extremely shallow.

On Oct. 2nd he had slept fairly; lay on his back, sometimes with knees raised, sometimes down; slight pain and tenderness chiefly in epigastrium; abdomen as yesterday; respiration 38, thoracic, but much less shallow than last night; temperature 98°; skin moist; pulse 138, stronger and better volume; tongue moist, covered with white fur. Took plenty of milk. On the 3rd he had slept the greater part of the night, but in the morning he complained of pain on the left side of the chest; abdominal wall hard; abdomen slightly tympanitic, but no marked swelling; no tenderness anteriorly, and no abnormal dulness; respiration 30, entirely thoracic; pulse 120, steadier and stronger; temperature 99°; skin moist; tongue furred, moist; no sickness; bowels confined. 8 P.M.: Pain in left side very severe; respiration 40, very jerky and shallow; temperature 101.5°; pulse 140; chest somewhat hyper-resonant anteriorly; breath-sounds exaggerated, and some moist râles; patient not in a condition to be lifted to examine back. On the 4th he complained much of pain in the left side; face looked pinched; no cough nor expectoration; respiration 82, very shallow; pulse 182, stronger than last evening; temperature 101°. The breathing became rapidly more impeded, and the patient died in the afternoon.

**Necropsy.**—Abdominal cavity contained about a pint of fluid blood, one or two coils of small intestine slightly granular on surface, and the whole somewhat distended by flatus, but no further signs of peritonitis. At the right extremity of posterior border of the liver a laceration existed, a bruised portion of tissue occupying an area about the size of a small orange extending into the substance of right lobe; this was of an ochre-yellow colour, and internal to it were several fissures in the apparently healthy hepatic tissue containing blood-clot; externally it formed one of the boundaries of an incomplete cavity, the walls of which were made up in addition by the anterior fold of the coronary ligament, the diaphragm and the right supra-renal capsule, together with some recently effused lymph. This cavity contained fluid blood and debris, and the walls were deeply bile-stained. The hepatic veins leading from and traversing the bruised area were occupied by firm dark blood-clot, and this condition was found to extend back as far as their entrance into the inferior cava, the lining membrane of the veins being roughened and vascularised. On microscopical examination the yellow area of hepatic substance was found to be in the condition known as "coagulation necrosis," and the walls of the hepatic veins and the tissue surrounding them largely infiltrated with small-celled inflammatory new growth. The other abdominal organs were normal. Lungs: The lower lobes on either side were much collapsed, and at the extreme base completely void of air, sinking in water. In the upper part of the lower lobe on the left side was an infarct, about the size of a small orange, wedge-shaped, with the base abutting on the surface, and in the main branch of the pulmonary artery to lower lobe was an embolus about three-quarters of an inch in length, decolourised, not attached to the arterial wall, and when incised disclosing a central cavity containing softened matter; this embolus apparently having its origin in the thrombosis of the hepatic veins. The left pleural cavity contained a considerable effusion of blood-stained fluid, while recent lymph covered the pleural surface of the infarct, also united the lower part of the fissure and covered the entire base of the lung, which was adherent to the diaphragm. Right pleura, heart, and pericardium were normal.

**Remarks by Mr. MAKINS.**—The above case is recorded as affording an example of a termination to a rupture of the liver not often described, and of which mention is omitted in most of the text-books, although the arrangement of the veins would seem particularly favourable to its occurrence. The patient had escaped the primary dangers of shock, hæmorrhage, acute septicæmia, or severe peritonitis; and although still liable to the supervision of the two latter, yet, in the absence of the pulmonary complication dependent on the thrombosis and subsequent embolism, he undoubtedly stood a chance of recovery; the more so since reparative processes preparatory to the localisation of the damage had already commenced at the seat of injury.

## BRISTOL ROYAL INFIRMARY.

NOTES OF A SEVERE CASE OF STRAMONIUM POISONING;  
SUBCUTANEOUS INJECTION OF MORPHIA; RECOVERY;  
REMARKS.

FOR the following interesting notes and remarks we are indebted to Dr. Alfred Lendon, house-surgeon.

On August 10th, 1882, Rosina J—, aged seven, whilst at play with two sisters in a suburb of Bristol discovered some green berries, of which the three partook freely. Rosina, however, eating more than the other children. She returned home shortly after, and was noticed to be strange in her manner. Soon she became slightly, and finally very, delirious. On learning that she had eaten something, her parents gave her an emetic of mustard, and then took her to a surgeon, who administered another of sulphate of zinc, neither of which acted. She was admitted into the Royal Infirmary, under Dr. Shingleton Smith, four hours after the occurrence, and her friends produced some leaves supposed to belong to the plant the berries of which she had eaten, this was recognised to be stramonium (*datura stramonium*, or thorn apple). Her symptoms were those of acute deliriant poisoning. The child was unable to answer questions, was extremely restless, rolling her head from side to side, and throwing her limbs about, so that she could scarcely be restrained in bed; she was talking incessantly and incoherently, and did not seem to recognise her friends, but evidently had spectral illusions. She was constantly picking the bedclothes and pawing the air. Her pulse was very rapid, her face flushed, and her eyes were frequently squinting, but not in any definite direction; the pupils were widely dilated. Her breathing was rapid, but not laboured; its rate, and that of the pulse, could not, however, be counted, as she was so restless. An emetic powder, containing ipecacuanha and antimony, was administered in water, but failed to act, whereupon one-twenty-fourth of a grain of apomorphia was injected under the skin, which had almost immediately the desired effect. In the vomit at least 100 stramonium seeds were found, together with portions of the seed capsule, mixed with partially digested food. As her symptoms showed no signs of abating, and were very alarming, one-sixth of a grain of acetate of morphia was injected hypodermically after about twenty minutes' interval. This had the effect of quieting her in a few minutes; she soon slept; the pupils became of moderate diameter, though not contracted; the strabismus, however, continuing for four hours. When seen next morning she was much better, having passed a quiet night; there was no delirium, the strabismus had ceased, but the pupils were again widely dilated. The temperature, pulse, and respiration were normal, and also the urine; the skin throughout had been dry, in spite of her exertions, but no rash was seen, and the child did not complain of dryness of the throat. On the 11th she was sick twice after taking purgative medicine, more seeds being brought up, and when purged later on in the day, the stools also were found to contain seeds. On the 12th she was sick again, and seeds were still found. Subsequently nothing worthy of note occurred, and the patient was discharged on the 18th.

When shown a thorn apple the child recognised it, and stated that she had eaten the contents of ten. Her two sisters were also ill and rather light-headed during the night, but they recovered without any special treatment beyond emetics administered by their mother.

*Remarks by Dr. LENDON.*—The recorded cases of poisoning by stramonium are very rare, and I am unable to look up the particulars of two instances reported in 1837 and 1872, which are mentioned in Dr. Neale's "Digest." All that seems to be known is that while the symptoms closely resemble those of poisoning by belladonna and hyoscyamus, they commence sooner, are more severe, and terminate fatally in a shorter time. The only symptom which appears not to have been noticed usually in poisoning by these drugs is strabismus; on the other hand, no erythematous rash was seen, and no dryness of the throat or thirst was complained of. With regard to the quantity of the poison taken, the child's statement probably cannot be relied upon, nor have we any means of ascertaining whether it was even a fatal dose, but that the quantity was very considerable must be assumed from the alarming severity of the symptoms;

moreover, as the seeds were not altered in appearance, and presumably had not been acted upon much by the gastric juice, it is probable that only a small amount of the active principle which was actually present in the stomach had been absorbed into the system. The chief points of interest in the case, however, are the decided antagonism manifested by morphia to stramonium, both as regards the delirium and the condition of the pupil, and the speedy and complete relief afforded by this moderate dose of morphia. It may be objected that as the other children recovered without any special treatment, so, too, this child might have recovered; on the other hand, it must be remembered that they were not considered bad enough by their parents to be brought up for advice. It is also worthy of note that seeds were vomited as long as forty hours after the poisoning, the patient having been sick on three previous occasions, so that implicit reliance could not be placed on emetics only. I am unable to ascertain whether morphia has been previously used as an antidote either in human beings or in experiments upon animals. In the fourth edition of Guy and Ferrier's "Forensic Medicine" it merely says that the use of morphia is worthy of trial.

## WEST BROMWICH DISTRICT HOSPITAL

CASE OF EARLY PERFORATION IN TYPHOID; REMARKS.

(Under the care of Mr. LANGLEY BROWNE.)

FOR the following notes we are indebted to Mr. F. F. German, resident medical officer:—

T. G—, aged eighteen years, presented himself in the out-patient department on the morning of September 27th. He had journeyed between two and three miles, having walked a considerable portion of it. He was suffering intense pain, which he referred to the region of the abdomen, the walls of which were flaccid; his face was vacant of expression, pulse weak; he walked with difficulty, and had been ill ten days. The bowels had been moved daily, but the evacuations were "frothy, sometimes streaked with blood." He was admitted to the wards and four minims of the official solution of morphia were injected hypodermically. This gave him great relief. Examination revealed nothing further; there was no increase of temperature, no other history than above obtainable, and the diagnosis was consequently a matter of some doubt. In the evening the pain referred to the whole surface of the abdomen again became very severe, and marked tympanites ensued. Between two and three ounces of clear high-coloured urine, containing one-eighth albumen, were drawn off. The patient expressed relief, and subsequently conversed freely. About 9 P.M. he was observed to put a finger of each hand in his mouth, as though to widely extend it, and was writhing in great pain. This modified, but he rapidly sank, and died at 10.30 P.M. the same night.

*Necropsy, the following afternoon.*—In the thorax were extensive pleuritic adhesions on the left side, and the cavity of the heart were nearly empty. On opening into the abdomen a large quantity of chylous fluid escaped; the peritoneum was sticky and slightly adherent, and the small intestines were distended to nearly size of large. The ileum was much congested, and on its inner surface were several small typical ulcers, one of which, about three and a half feet from ileo-caecal valve, perforated the bowel and was still patent. The other organs were healthy.

*Remarks.*—Perforation has been estimated to occur in from 1 to 2 per cent. of the entire number of sufferers from typhoid, and of the fatal cases has been variously stated to have occurred in from 8 to 12 per cent. As to the time of occurrence and situation of this accident, there are but few reliable statistics. In those tabulated by Hoffmann, 9 per cent. only occurred at the end of the second week, while 27 per cent. happened between the eighteenth and twenty-first days, a similar number at the end of the fifth week, and the remainder subsequently. In 77 per cent. of these same cases, the perforation occurred at a spot not exceeding twenty inches above the ileo-caecal valve, and in about 11 per cent. only at the same distance as in this case. I would add, that twelve days previously the boy had been at work, and during his illness, though at times in considerable pain, was not confined to bed. Was it the typhoidous ambulations of some authors?

## BEDFORD GENERAL INFIRMARY.

A FISH-HOOK IN THE OESOPHAGUS; EXTRACTION;  
RECOVERY.

(Under the care of Dr. GOLDSMITH.)

FOR the following notes we are indebted to Mr. E. A. Laurent, M.B., resident surgeon.

F. P., aged ten, of Great Brickhill, Beds, whilst engaged in fishing held in his mouth a fish-hook attached to a piece of gut, and accidentally swallowed it. He was admitted to the infirmary eleven hours after the accident, under the care of Dr. Goldsmith, senior surgeon to the institution.

The only subjective symptom on admission was pain over the episternal notch. Half an inch of gut was seen protruding from his mouth, and on following the gut backwards with the finger, the notion conveyed to the touch was that the hook lay somewhere in the windpipe, but the boy had no cough, no dyspnoea, and his voice was perfectly clear. On applying gentle traction to the extremity of the gut, great resistance was felt. This was consequently discontinued and chloroform administered. A piece of silk ligature was tied to the end of the gut, and to the extremity of the silk a fine wire was attached. A traveller fourteen inches long was then passed along the twisted chain of iron wire, silk, and, lastly, gut down the oesophagus. It, however, proved to be too short to reach the hook; it was therefore withdrawn and a full-sized oesophageal bougie substituted for it. This passed with perfect ease until it reached the bend of the hook; here slight resistance was felt, which was easily overcome by pressure. During this part of the operation the bougie touched the cardiac end of the stomach and vomiting was induced, although the insensibility was nearly complete. The bougie was kept in position and the wire tightened; both bougie and hook fixed at its extremity were carefully withdrawn without any further trouble. The hook proved to be a No. 6 perch, and the gut was nine inches and a half long.

## Reviews and Notices of Books.

*The Diseases of the Spinal Cord.* By BYROM BRAMWELL, M.D., F.R.C.P. Edin. Pp. 300. Edinburgh: MacLachlan and Stewart. 1882.

THIS work consists of four chapters. In Chapter I. the author introduces us to the "anatomy and physiology of the spinal segment." "The spinal cord," Dr. Bramwell writes, "may be said to consist of a series of segments placed one above another. Each segment comprises the portion of cord to which a pair of spinal nerves is attached, and each segment may be viewed as a distinct spinal unit, or, to speak somewhat figuratively, as a distinct spinal cord for a definite area of the body—viz., that portion of muscle (muscular area) to which its anterior roots proceed, and that portion of skin, tendon, muscle, mucous membrane, viscus, &c. (sensitive area), to which the fibres of its posterior nerve-root are distributed." The mode in which the author thus introduces us to the anatomy, and proceeds in the same way to the physiology and pathology of the spinal cord through the medium of a single segment of it, is philosophical, and tends much to clearness of explanation. Once let us obtain a good idea of the structure and relations of a single segment, and but little more than an act of multiplication is requisite to fill the mind with true notions regarding the cord as a whole. The spinal cord lends itself remarkably well to this mode of examination and description, which would be far less easy, if not impossible, in the case of the brain. The various intra-medullary and extra-medullary lesions having been considered from an anatomical and physiological point of view, Dr. Bramwell enters very fully and with much lucidity of description upon the important subject of case-taking. The method of examination which he advocates is clear and to the point. We quite agree with his remark that "a methodical plan of

case-taking is essential for scientific purposes, and it would be most advantageous if physicians could agree upon a uniform system." Under the "clinical examination of the spinal cord" a concise account is given of the various symptoms which are met with, and their significance; the distribution and the amount of paralysis; practical directions as to the mode of applying electricity in the diagnosis; remarks upon the mechanical irritability and tonicity of the muscles; the condition of the reflex movements, including a very clear account of the vesical reflex and the disturbances to which the action of the bladder is liable; the rectal and sexual reflexes. The sensory functions of the spinal segment are next considered, and the various disturbances of these described. A couple of pages are well devoted to the subject of "path referred to the spinal column," a point which we believe is constantly giving rise to mistakes. The question of the diagnosis in diseases of the spinal cord receives, as it deserves, full attention, and many valuable hints are contained in the portion of the work relating to this subject. Some good remarks also occur in reference to prognosis, a subject upon which, unfortunately, in the nature of things, there is not very much to be said of a satisfactory character. The same remark may perhaps be applied to the question of treatment. What little there is to be said upon this matter is sensibly put, and exaggerated estimates of the power of therapeutics in chronic disease of the nervous substance are properly avoided.

The fourth chapter contains a tabular classification of the diseases of the spinal cord arranged after the plan, though differing very considerably in its details from that, introduced by Grasset of Montpellier. We notice here a reference to what the author calls "indiscriminate lesions" of the anterior cornu. The following remarks on this subject appear to us very pertinent: "The anterior cornu may, like any other part of the transverse section, be affected by indiscriminate lesions. Other parts of the transverse section are usually involved; the symptoms are then compound, being partly due to the lesion of the anterior cornu, partly to the lesion of the other parts which happen to be affected." From want of remembrance of these facts cases of disseminated sclerosis are very frequently misunderstood. For instance, a patch of sclerosis involving the anterior cornu at a certain level will give rise to muscular atrophy in the district to which the motor roots arising in that particular segment are distributed. The observer, perhaps, makes a diagnosis of progressive muscular atrophy, and this because he fails to notice that there is anæsthesia at some other part of the body, arising from a patch of sclerosis involving the sensory side of the cord at another point. The tabular classification is followed by a short description of the individual organic affections, differential diagnosis being especially dwelt upon.

Dr. Bramwell's book is profusely illustrated. Believing that one great secret of all successful teaching is to instruct by the eye as well as by the ear, the author is in the habit of copiously illustrating his lectures by diagrams, drawings, and microscopical illustrations. The diagrams and drawings which are here introduced into the text by means of woodcuts, and the microscopical sections which are represented in colours, are excellent specimens of art. The sections of the cord are very true to nature, and we are especially pleased with the sketch diagrams, which are very numerous and effective. These are of great help in the elucidation of a subject which is often of so difficult a kind as to need all the aid which can be given by graphic illustration. The sketch diagrams and the concise tables of differential diagnosis constitute a special and acceptable feature of this book. No doubt the work is not exhaustive as a treatise upon diseases of the spinal cord—indeed, for this would not many volumes be required!—but by a sort of rough analogy we may liken it to an excellent guide-book amply furnished with

charts and tables of ready reference, and sketch maps of the routes by the aid of which the traveller, be he ever so little acquainted with the country, will find his journey immensely facilitated, and will readily learn in what directions he may best concentrate his attention and powers of observation.

*Report of the Scientific Results of the Voyage of H.M.S. Challenger (Captains Nares and Thomson) during the years 1873-76.* Prepared under the superintendence of the late Sir C. WYVILLE THOMSON, and now of JOHN MURRAY. Narrative, vol. ii. Pp. 744, and 29 with one plate. Longmans, 1882.

THIS, the second volume of the general narrative of the voyage of the *Challenger*, has been first published because it had been nearly completed by Sir C. Wyville Thomson before his lamented death, the present editor, Dr. Murray, thinking it was better not to postpone the publication of the scientific results it contains. The subjects treated of in the present volume are—1. A memorandum on the magnetical observations made during the voyage by Sir Frederic Evans. 2. Magnetical instructions. 3. Abstract of magnetical observations during the voyage. 4. Abstract of magnetical observations made at land stations, prefaced with descriptive references to the positions (observation spots) of the instruments. 5. Abstract of variations of the compass observed at sea. 6. Abstract of observations with Fox circles. 7. Memorandum on the meteorological observations made during the voyage by Staff-Commander Tizard, R.N. 8. Abstract of meteorological observations. There are also two appendices—one by Professor Tait on the pressure errors of the *Challenger* thermometers, and a second by Professor Renard on the petrology of St. Paul's Rocks.

In view of the exceptionally good opportunities afforded by the voyage for taking magnetical observations, the ship was elaborately fitted with instruments rendered practically free from error at Kew, and the influence of the ironwork of the ship on which was carefully estimated before starting. At each land station touched at, the absolute declination, inclination, and horizontal intensity of the magnetic force were determined, and at sea observations of the three elements were taken daily. About 74 of the former and upwards of 600 of the latter observations were taken. The magnetical instruments supplied to the ship were a portable unifilar magnetometer for determining the absolute horizontal intensity and the declination on land; a Barrow's circle with two reversible needles for determining the inclination on land; a Kater's azimuth compass, with levelling table, for determining the declination on land; Fox's apparatus or circle, for observing the magnetic inclination, and force at sea primarily; a gimballed table complete, adapted for Fox's circle, as to be used at sea; a compass bowl and standard cup, and a small vibrating needle for determining independently the ship's mean horizontal force to the north.

No less than 724 pages of this volume are occupied with the records of the observations made with these instruments, and are a wonderful example of continuous and careful work. They will prove of immense value to all who are interested in the great problems of magnetism.

Professor Tait's memoir on the pressure errors of the *Challenger* observations is very interesting, and, as he remarks, his inquiries have led to many curious offshoots: as, for example, the determination of the amount of heat developed in different substances by exposure to very high pressure under different circumstances; the cause of the breaking of a piece of glass or other fragile body under hydrostatic pressure; the accurate measurement of pressures greater than can readily be compared with the weight of a tall column of mercury. Amagat has, it appears, successfully worked with a column of mercury 1000 feet high, corresponding to a pressure of about three tons weight per

square inch; but Professor Tait describes an apparatus which is capable of giving results of considerable accuracy up to pressures of twelve tons weight per square inch.

Professor Tait points out various defects in the instruments and corrections employed in the determination of the temperature at great depths. He calculates that the internal capacity of a glass tube with thick walls and small bore is reduced by about 1-1000th part for each ton weight per square inch of pressure applied from without, the ends being closed; and his calculation was verified by experiment, a result that considerably modifies the corrections for pressure that were made on board the *Challenger*.

The report on the petrology of the barren rocks of St. Paul in the Atlantic, by the Rev. A. Renard, is interesting. Darwin gives an account of them in his "Voyage of a Naturalist," and in his geological observations describes them as rocks which rise very perpendicularly from the sea. The *Challenger* observations show that they have a vast plain on their eastern side, the depth of water on which varies from 2500 fathoms to 1425 fathoms. Darwin comments on the peculiar structure of these rocks, and is indisposed to regard them as volcanic. The Rev. A. Renard, however, arrives at the conclusion that the rocks, though presenting many peculiarities, are really of igneous origin.

*Therapeutical Remembrancer.* Presenting in detail all Medicaments accredited by the British Pharmacopœia; with copious Supplementary Tables, offering or recalling suggestions of resource from the "Materia Medica," interspace being provided for private notanda, &c. By J. MAYNE, M.D., L.R.C.S.E., L.S.A. Second edition, revised. London: J. & A. Churchill. 1882.

THE information contained in this work is of a most peculiar description, and we much fear that any student who adopted the "suggestions" of the author would find himself in trouble. Under the head of "Alteratives and Deobstruents," we find bromine recommended for internal administration in *eighty-grain doses*, and we are told that it is to be given in solution. This is very startling, and we were in hope that the author had temporarily confounded bromine with bromide of potassium or bromide of ammonium; but this is not the case, for the dose of these salts is correctly given on the same page. The author's views on therapeutics are certainly original; at all events, they are not shared by the majority of the profession. We have judged his book by a not very high standard, and have found it wanting. Even in the most elementary work on therapeutics we should expect to find some reference to the use of quinine in ague, and of sulphur in the treatment of scabies; but on these subjects the author is strangely silent. The therapeutic action of sulphate of quinine is summed up in the statement that it is used "in an infinity of cases where restorative energy is urgently necessitated." We are told that it may be given "in solution," but we are not told what solvent should be employed. Surely it would be better for a student to know that sulphur is used to cure the itch than that "it was an esteemed medicine among the Greeks, Arabs, and Hindoos." Nuxvomica, we find, is used in "gout, rheumatism, dyspeptic complaints as a nervine stimulant." Strychnia, too, is used in gout, although the author advises the "utmost consideration in its employment." Belladonna rubbed over the eyebrow or lid "expands the pupil;" whilst atropia is an active poison "intended only for external use." These are a few examples taken quite at random. We are sorry to have to speak thus of the book, but it is quite unreliable.

THE Sevenoaks Local Board has applied to the Local Government Board for permission to borrow £3000 to be expended on sewerage works.

# DR. RICHARDSON'S REPORT ON THE SANITARY CONDITION OF THE BOROUGH OF BRIGHTON.

To the Mayor and Corporation of Brighton.

Royal York Hotel, Brighton, Sept. 1882.

MR. MAYOR AND GENTLEMEN,—In compliance with the request conveyed to me by his Worship the Mayor, on July the 4th, I proceeded immediately to make a complete and independent Sanitary Inspection of the town of Brighton.

I have been enabled to make this inspection the more searching and complete from the circumstance that this is the second time in which I have had occasion to carry out the same duty. In the year 1864, at the request of my late friend, your distinguished townsman, Sir J. Cordy Burrows, I included Brighton in the list of towns upon which I was then reporting for my series of reports on the "Medical History of England," and in that year, 1864, I published at length the "Medical History of Brighton" in the *Medical Times and Gazette* for June 11th, 18th, and 25th.

This previous labour, while it familiarised me with the localities I have recently inspected on your instruction, has enabled me to make some very important comparisons bearing on the condition of Brighton as it was eighteen years ago and as it is at this present time.

The comparisons will appear, incidentally, as I proceed with this report, but I may state at once, generally, that in a sanitary point of view, the improvements which have been carried out in Brighton during the period which has elapsed since my last inspection, have been of the most satisfactory character. The authorities have evidently been incessant in their efforts to better the sanitation, and in the greater part of their efforts they have been signally successful. In cases where they have failed to carry out all that they have wished, the failure has arisen from no want of care or desire on their part, but from the fact that they have been working at a time when the details of sanitary science—details new to the world at large—have been undergoing development by what may be called the experimental attempt at success, a process of training which carries with it the necessity of getting at practical truth by the steady exclusion of practical error.

I, who during the whole period named have been daily engaged in sanitary work and progress, may venture, as safely as anyone living, to state that such experience in such work and progress was inevitable. I foresaw it, in 1864, as applied to Brighton, respecting which I then wrote: "The sanitary condition of Brighton, like that of most other large towns of the present day, is progressive, each step having to be determined by experiment before its adoption."

Coming back now to observe what has been done, I am surprised to find how much has been successfully done. At that time the water-supply was very good, but it has been so perfected that no town in the world can boast a freer, a more distinct, or a purer supply. In that day I found eleven miles of streets supplied with sewers, now sixty miles of streets are supplied. In that day cesspools abounded everywhere, now they are quite exceptional, and, where they exist, have no connexion with the water-supply. Thus in some of the most important of sanitary details there have been great and effective advances.

In proceeding with the present inquiry as to the health of Brighton at this time and in the recent past, I have devoted several weeks of research on the spot, taking nothing at second-hand, but making every inquiry personally. This report, therefore, may be accepted as based on direct observation.

In carrying out this research it occurred to me that the

most complete course would be to ascertain the following facts:—

1. What is the state of health in Brighton at the present time, including the schools (public and private), institutions, and hotels?
2. What has been the state of health in the recent past?
3. What is the present condition of the water-supply of the town?
4. What is the condition of the drainage and sewerage?
5. What is the state of the paving and roadways of the town?
6. What is the condition of the slaughter-houses, cow-sheds, and bakeries?
7. What is the condition of the common lodging-houses of the town?
8. What are the facts bearing on the rate of mortality of Brighton, and what causes have influenced and continue to influence that rate?
9. What improvements in sanitation are suggested by the research?

## HEALTH OF BRIGHTON AT THE PRESENT TIME.

As bearing upon the first subject of these inquiries—namely, the present health of Brighton,—I proceeded to make a direct investigation of the conditions of health that were manifested in the schools and other public institutions. I put myself into communication with the heads of schools, with the medical officers of the different medical institutions, with the superintendents of the charitable and other institutions, with the parochial medical officers, and with medical men who, by their relation to particular questions which were brought out by my investigations, were most able to afford me the necessary information.

The schools naturally called earliest for attention. They are the grand tests of sanitation in every place. If the sanitary condition of a place be fundamentally bad, the fact will, of a certainty, be declared in the young who are present in the schools.

I made known therefore a request, through the mayor, on the day of my arrival, that I should like, at once, to visit the leading educational establishments, and in a few hours I had so many requests for inspection that several days were demanded for the school inspection alone, and after all I fear that some schools to which I was invited were from pressure of time omitted.

In a letter addressed to the mayor, at his request, I stated what the result of this inspection had been up to the date of July 13th. I reported that I had found a condition of good health that was most remarkable; that the educational institutions of Brighton exhibited a freedom from contagious and indeed from all disease that was quite exceptional in my experience; and that the attention paid to sanitary details and supervision by the heads of the scholastic establishments I had visited was admirable and deserving of the warmest commendation.

The further and much extended investigation on this subject which I have been enabled to carry out since July 13th, fully confirms the statement given.

Of the private schools to which I had admission, I visited no less than forty of the largest, arranging my visits so as to include every district of the town in which such schools are situated. In the course of these inquiries I had the opportunity of ascertaining the sanitary condition of schools in which over eighteen hundred scholars—the young of both sexes being about equally divided in them—are undergoing education. Throughout the whole of the investigation I met with but one instance of disease of any kind. In one school, singularly healthy in every respect and provided with excellent sanitary details, a pupil who had been out of town on a visit had contracted chicken-pox, in a mild form. Beyond this, I could trace out no case of epidemic disease nor of any other kind. I need not comment on this evidence, because it speaks for itself. I doubt whether in the present state of sanitary science it would be possible to find anywhere a more striking proof of healthy life. I should further remark that the scholars in every instance bore the appearance of excellent health.

From the private schools I passed to the inspection of the Board Schools, and the larger of the Voluntary Schools. The Board Schools, ten in number, all of which were visited, hold a total school population at the present time of seven thousand four hundred (if all on the roll be included), with an average daily attendance of six thousand. In my visits I

had the opportunity of seeing the children in all the departments, boys, girls, and infants.

In the Circus-street Board School I found 100 girls in attendance, and 119 infants, with no sickness in anyone belonging to the school. The children of this school are very poor, their parents being, as a rule, of the poorest working class; they were consequently not so well clothed and fed as in some of the other establishments of the same kind, but they were, in point of healthy appearance, of fair average when compared with the same classes of school children in other towns. The school arrangements are good. The water-closets,—constructed on Macfarlane's system, in which a large body of water in the receiving part of the closet is regularly carried off twice daily,—are exceedingly clean and free from odour; the school-rooms are clean and well ventilated, and the arrangements altogether satisfactory.

The Finsbury-road School, the newest of the Board Schools in the town, was found with an attendance of 230 boys, 292 girls, and 364 infants. There had been a recent outbreak of measles in the homes of some of the children attending at this school, but it had subsided. I visited the children in their playgrounds, and it would be difficult to find anywhere a body of children of the same class who presented a better or healthier appearance. The arrangements of the school are excellent in every particular.

The same observations apply to the Middle-street School, in which I found 260 boys, 210 girls, and 180 infants in attendance; to the Pelham-street School, in which were 250 boys, 200 girls, and 300 infants; to the Lewes-road School, in which there were 198 boys, 150 girls, and 247 infants; and to the Preston-road School, in which there were present 267 boys, 150 girls, and 190 infants. The exercises of the children in musical drill at the Preston-road Schools were of the most striking character, and indicative of distinctively good conditions of physical health.

The Hanover-terrace Board School, presenting an attendance of 270 boys, 126 girls, and 173 infants; the Puget Schools, presenting an attendance of 200 boys, and 160 girls; the Richmond-street and Sussex-street Schools, in which there were 267 boys, 200 girls, and 250 infants; the St. John's School, in which there were 272 boys, 212 girls, and 214 infants, were all schools in which, as in the Circus-street School, the children were of a poorer class. These schools were, nevertheless, at the time of my visit, free from disease, and the sanitary condition was good. With the exception of one room in the St. John's School, in which the ventilation seemed less perfect than in the other rooms, and in which, in reply to the question, I was told that both masters and scholars sometimes suffered from headache, I have no fault to find; indeed, I was struck by the skill with which some of the changes in old buildings, which really ought to come down, have been carried out.

The Central National School, a voluntary Church school, under the direction of the Rev. J. J. Hannah, in which there were 276 boys, 140 girls, and 90 infants, was in an exceedingly healthy condition. The rooms are spacious, light, and well-ventilated, and the appearance of the scholars is quite satisfactory. The same observation applies to St. Margaret's School, in which there were 80 boys and 100 girls, and to St. Martin's, in which there were 154 boys, 200 girls, and 180 infants.

At the St. Mary and Mary Magdalene Sunday Schools in Broad-street I found everything plain but perfectly clean and healthy. In the scholars attending them there was no disease, and I ascertained that amongst them there had been no fatal case for four years past, and then only one, the cause of death being pulmonary consumption.

Passing from the schools to other public institutions in which the young are located and educated, I inspected the following and add the results:—

In St. Mary's Hall, Kemp-town, 100 clergymen's daughters are received and educated. At my visit to this admirably conducted institution the scholars were away for their vacation, but I learned that since the year 1874 they had been free from any outbreak of contagious disease. In the spring of the present year some of them had suffered from headache, with lassitude and failure of appetite, without fever, eruption, or any symptom of acute febrile disease. The illness was for some days pretty general, and some of the scholars were slow in resuming their natural aptitude for study, although none of them were at any time in danger. The house is situated on a fine elevation, and the utmost care has been taken to make the sanitary condition perfect. The exit drains from the house have been separated from the dwell-

ing, the soil pipes are ventilated, and the water from the baths and offices is discharged into the open air before entering the drains. The rooms, dormitories, and lavatories are excellently fitted, and there is a commodious and isolated ward for the sick.

In the Blind School, in which thirty-one children (sixteen girls and fifteen boys) are brought up, I found that there was entire freedom from disease, and that for two years and a half past there had been uninterrupted good health. At the time of my visit the children were away for their holiday, and I had not the advantage of seeing them personally; but all the arrangements of the school were excellent.

In the Deaf and Dumb Institution the pupils were having their annual holiday at the time of my visit; but I learned that for the past forty years there had not been a single instance of an outbreak of epidemic disease commencing within the school itself. It has occasionally happened that contagious disease has been directly introduced into the school. Measles has entered, and scarlet fever was recently introduced in this way. Under these circumstances the sick have been immediately isolated and removed from the house, by which the further spread of the disease has been prevented.

Taking them as a whole, the educational establishments of Brighton afford unmistakable evidence of a present state of good health that could not be surpassed. My inspection included observations in institutions in which certainly not fewer than ten to eleven thousand of the population, or a tenth of the whole resident population, receive daily educational training, and in that whole I did not find one case of serious disease. Further, of those who were absent from illnesses of all kinds, I was only able to trace nine altogether, or less than one in the thousand.

From the schools and educational establishments I carried my inquiries to those establishments in which persons of both sexes are provided for during convalescence or disease, or while being trained to some industrial or useful art. These institutions are excellent tests of the health of the place in which they are situated. The persons who are resident in them are often feeble from want of comforts and ease in early life. Some are sick. All, in a certain degree, are more than ordinarily liable to disease.

In St. John's House, a convalescent home for children, I found twenty-eight little boys and girls, nearly equally divided, in various stages of recovery from lingering illnesses. These children are sent to Brighton from different parts of the kingdom for the sake of the change, the treatment, and the sea air. They were all sickly children, as is implied by the nature of their residence here, but the greater number were improving in health, and were enjoying, with much relish, their seaside walks. There was no case of contagious disease, and there had been none for a period of three years. Three years ago a case of scarlet fever was imported from London, but under immediate isolation the spreading of the disease was prevented.

In the Home for Invalid Children (70, Montpelier-road), I found twenty-one children, all of whom were subjects of some form of chronic constitutional disease. There were representatives of both sexes in the institution and all were entirely free from infection. There had not been an outbreak of infectious disease in the place since its foundation, twenty-five years ago.

In the Home for Orphan Boys (46 and 49, Buckingham-place), I found forty boys who were housed and taught. There was no disease, and, except that a case of gastric derangement assumed symptoms of modified typhoid, twelve months ago, there has not been a case of zymotic affection in the institution. The house is beautifully clean, every bedroom is specially ventilated, the water-closets, offices, and bath-rooms are in excellent order, and the drains are entirely cut off from the house. There is a special sick-room, away from the dormitories, which is set apart to receive at once any child that is taken unwell. This admirable plan is common. I may observe, in all the educational establishments where scholars are in residence.

In St. Mary's Hospital, Queen-square, I found what may be called a religious house, something like the houses that were maintained by the religious of the Middle Ages for the feeble in mind, body, and estate. It is, I was given to understand, one of the Rev. A. D. Wagner's High Church Charitable Institutions. It consists of one side of a street of houses, ascending from a low to a high level, the houses being made to communicate with each other. Considering

that this hospital has, so to say, been improvised, it is remarkably well and skilfully arranged. Every part of it was thrown open, unreservedly, for my inspection. I found the hospital containing 230 inmates. Fifty of these were fatherless, motherless, or poor children; fifty were aged women; fifty were women who had been rescued from unfortunate lives; fifty were persons in training for domestic or other service, or for needlework or some useful occupation; and the remainder were attendants, superintendents, or training scholars not included in the classes named above. I found the most admirable order everywhere prevailing in this establishment, and the greatest care taken in respect to the sanitary details. The living rooms and bedrooms, though small, were free from unnecessary furniture, neatly and tastefully furnished, and exquisitely pure and clean. The lavatories, closets, and offices were well arranged, and the laundry, which is on a large scale, was fitted with every contrivance for securing effective and wholesome cleanliness. It is, in fact, a public laundry on a very good principle, and if it were provided with a separate apartment in which clothing, coming from houses in which there is infectious disease, was subjected to a disinfecting degree of heat before it went to the laundry proper, the place would be a model public laundry. As it is I wonder that it is not in demand beyond any requirement it could at this moment fulfil.

The inmates of St. Mary's Hospital were entirely free from disease at my visit, and had been free in an exemplary manner for long past. They had never suffered from any outbreak of an infectious character, and they bore the appearance, generally, of persons in as good health as they could be under the conditions in which their lives had been cast, the young especially.

The lady superior keeps a careful registry of what befalls the inmates under her care, and at my request she was kind enough to take it down and let me calculate the deaths that had occurred during the past ten years—namely, from July 19th, 1872, to July 4th, 1882. The deaths were at the rate of four a year, ten of which, at ages ranging from sixty-three to eighty-seven, including three octogenarians, sank from the paralysis of senile decay, finding in fact in the hospital a refuge for their declining days. The hospital presents, through these facts, a striking illustration of healthiness. Its inmates come from those who are worst provided for. It is not at all favoured by position; it is close to the large disused burial-ground of the old church, and being constructed out of a number of small houses it has had no special advantages of an architectural kind. It, nevertheless, has represented a low general mortality, and an infant mortality, in children under five, of seven deaths in ten years. It has been visited by no epidemic whatever.

The Percy Almshouses, which receive twelve inmates, all women, and chiefly those of advanced life, are most healthy and in good condition, clean, neat, and wholesome. They were entirely free from any contagious disease, and had been for a period as long as I could trace back—namely, twelve years.

The Home for Training Neglected Girls in Warleigh-road I found containing twenty-two inmates, young girls who are learning the duties belonging to domestic service and other useful occupations. The house was exquisitely clean and comfortable. It is well and scientifically drained, and it has good sleeping accommodation. There has never been any epidemic in it, and the girls under training, who were introduced to me, were in excellent health.

St. Andrew's Home, in Egremont-place, is a residence provided for eight youths who have no home of their own. The house is small, but very clean. It is an ordinary house, and for the purpose which it serves the most that could be made of the accommodation has been made. In my opinion there is barely sufficient space, and I find that a better and more convenient house will soon be secured. There has been no disease of an epidemic character, nor any other of a serious character in the house. The inmates were all very healthy and seemed to be, truly, in a place where they enjoyed the privileges of home.

The Needlewomen's Home, in the Dyke-road, receives nine inmates, all of whom are suffering from some bodily deformity, and most of whom are, necessarily, very feeble. The house is a model of cleanliness and comfort, and the sanitary arrangements are good throughout. There has been no case of infectious disease for many years, at least, and probably none from the commencement of the institution. An unusually good condition of health prevailed at the time of my visit.

Albion Hill Home, called commonly Mrs. Vicar's Home—after the name of the generous and noble-hearted lady who has been from the first its mainstay—receives young girls who are reclaimed from degradation and poverty. It consists of a home, in which there are sixty-two dormitories, a sewing room, and a large public laundry, with other rooms attached; a probationers' cottage, containing nine dormitories and rooms, in which the needlework and laundry work of the establishment are done; of the Princess Alice Memorial Cottage, where public needle and machine work are carried out, and in which there are fifteen dormitories; of the London Cottage, for inmates from London, containing fourteen dormitories and rooms, in which hopeless and helpless girls can be taken in at a moment's notice, and cared for until they can be received into a home permanently; and of the servants' home, in which the man servant of the home and his wife reside, and the upper part of which is occupied by young servants, who, being out of place, are seeking for new situations. The objects of this most useful and beneficent institution are carried out admirably, and if the occasion were befitting I should speak of it as I feel for the object's sake. As it is, I can only report that I found at my visit universal good health, that I could trace no instance in it at any time of epidemic disease, and that the sanitary arrangements and details are of the most praiseworthy character.

The summary of the evidence derived from the inspection of the above benevolent institutions confirms the evidence afforded by the schools. The inspection revealed an unusually healthy condition, an unusual freedom from spreading and infectious disease, and a sanitary supervision everywhere which is on a level in all instances with, and in many instances superior to, that which is common in other English towns. No mind, free from bias, could draw from these institutions any other deduction than that they betoken the possession of every advantage for general health and marked freedom from exceptional outbreaks of disease.

From the public institutions above noticed my attention was next directed to the medical institutions where the actual sick receive treatment for their diseases. In these institutions we find always sound information respecting the health of the localities in which they are situated, while their museums, though they contain only the dead evidences, speak the nature of the prevailing diseases. I made, therefore, special inquiries relatively to the evidence that could be gathered from these sources of information.

The Sussex County Hospital, situated at Kemp-town, contains thirteen wards for medical and surgical cases, and a male and female fever ward. In my report on the hospital in 1864 I expressed an opinion that the mortality of this institution was rather in excess of some other provincial hospitals that had at that time been renowned for their low mortality, and I particularly cited that of Norwich in comparison. In the ten years previous to 1864 the number of patients admitted into the Sussex County Hospital had been 1165 annually, and the annual death-rate had been seventy-five. This yielded a death-rate of 6 per cent., or 2 per cent. above what had been represented at Norwich. Afterwards the position of the two hospitals changed in favour of Brighton, and the Brighton hospital fairly holds its own in comparison with other similar provincial institutions. In the report of 1864 I dealt on the comparative freedom of the hospital from cases of epidemic and contagious disease, and I still find that it enjoys a similar freedom. At the time of my present visit there were no causes whatever that added to the ordinary sickness or mortality in any department; on the contrary, the number of cases of serious disease were unusually small, and there was almost entire freedom from diseases of the zymotic or contagious class. Mr. Scott, the resident surgeon, who was good enough to look up for me the number of zymotic cases, reported to me that since the beginning of the present year there had been, from January 1st to July 15th (twenty-eight weeks), 23 cases of scarlet fever, 3 of measles, 10 of typhoid, and 1 of erysipelas. Compared with the average number of cases occurring in periods of time of the same length during the preceding five years, these returns show the rate of zymotic disease in the present year to July 15th to have been in the proportion of 37 to an average of 36.2 in the preceding periods. The very rare occurrence of typhus fever, diphtheria, erysipelas, and pyæmia or surgical fever are the best indications that the hospital is well provided with pure air. The record before me for the past six years shows only 1 case of surgical fever, 1 of typhus, 5 of diphtheria, and 13 of erysipelas, the

last-named being in every instance examples of erysipelas of the face, a form of disease to which many persons are specially predisposed.

The mortality of the cases of zymotic disease in the hospital is a further study which deserves attention. In the five years and twenty-eight weeks—viz., from January, 1877, to July 15th, 1882,—the cases of zymotic disease which are on the record before me, include typhus, 1; pyæmia or surgical fever, 1; scarlet fever, 230; measles, 33; typhoid, 87; erysipelas, 13; rûtheln, 4; diphtheria, 5. Total, 374. The number of fatal cases of this total was 30, yielding a rate of 8 per cent. An analysis of these general results is also deserving of study. The one case of typhus died. The one case of pyæmia died. Of the 230 cases of scarlet fever, 218 recovered; 12, or 5·2 per cent., died. Of the 33 cases of measles, 31 recovered; and 2, or 6 per cent., died. Of the 87 cases of typhoid, 73 recovered; and 14, or 16 per cent., died. Of the 13 cases of erysipelas, all recovered. Of the 4 cases of rûtheln, all recovered. And of the 5 cases of diphtheria, all recovered. I need not point out to sanitarians that such results as these could not possibly have been obtained, under the pressure of such dangerous and fatal diseases, in other than an air pure and exceptionally favourable to life.

The Royal Alexandra Hospital for Sick Children was the next of the medical institutions to which my inspection extended. This is a newly built hospital, on a site admirably selected. The house stands so high that it is visible from almost all parts of the districts surrounding the town and from the sea along the whole line facing the town. The building has been fitted up with every consideration for health, and may be accepted for the present time as a model institution. The ventilation, the warming, the arrangement of the waterclosets and offices, and the modes of cleansing leave nothing to be practically desired, while the walls of the wards, lined with artificial marble, can be cleaned like porcelain. I found no case of infectious disease in the institution on the occasion of my visit, and the record of cases during the twelve months in which the hospital has been opened showed that two forms of epidemic disease alone had occurred in it. There had been eight cases of measles, attended by one death, and two cases of mumps, both of which had recovered.

The Lying-in Charity of Brighton, situated in West-street, was included in my inspection, because the condition of health of those who go through the great "pain and peril" is always an index of the good or bad sanitary state of the place in which the process of childbearing takes place. It is now well-known that childbed women, even amongst the classes of women most cared for, are singularly susceptible to diseases of a serious type, such as scarlet fever, erysipelas, puerperal fever, milk fever, and peritonitis. Here, then, is an institution well worth careful study, a test institution of salubrity or insalubrity. The institution affords gratuitous attendance and assistance to poor married women in their own homes, advice and assistance to women suffering from uterine diseases, and to infants suffering from any form of disease. It also admits within its walls a limited number, not exceeding five, of poor women during their confinement. The greater part of the special attendance on the women is by midwives, who, in emergency, summon the assistance of one of the members of the medical staff.

At the time of my report upon this institution in 1864 I found that, since its establishment by the late Dr. Lyons, in 1830, the number of 13,309 women had been attended during delivery, a rate of 391 per year. The number in 1863 was 740, and the numbers that have been attended since the foundation amount to about 27,000. They reach now about 900 annually, the patients residing in the poorest parts of the town and being all too poor to obtain their own paid attendant. In the institution itself I found good wards and all necessary conditions for health. For many years past there had been no contagious form of disease. On inquiry into results of attendances outside the hospital I ascertained that they also had been remarkably good. In 1882, as in 1864, I could find no evidence of the occurrence of an outbreak of any kind of contagious disease amongst the patients who had been confined at their own homes since the opening of the institution. Mr. Goode, the resident surgeon, reports to me that, during the past two years with which he has been connected with the institution, he has not had a single case of scarlatina, small-pox, or erysipelas, and only one of peritonitis amongst the patients attended at their own homes.

The Dispensary, in Queen's-road, was another medical institution to which I directed my researches. The dispensary does not receive patients within its walls as in-patients, but it issues annually letters for treatment in its out-patient and visiting department, to the number of from eight to nine thousand, to persons in the various districts—northern, central, southern, and eastern—of the town. The returns of the dispensary afford therefore a most important index of the health of, and of the diseases prevailing amongst, the poorer classes. The difficulty in utilising the information thus rendered is considerable, owing to the circumstance that one patient may have his or her letter renewed several times during one illness, as letters have to be renewed every month, but I am indebted to the resident surgeon, C. B. Richardson, M.B., for an able statement, in which this difficulty is, as far as possible, avoided.

At my visit in July the number of persons under treatment at the dispensary was very small, and the presence of infectious disease was reduced to a low figure. I found, however, that during the early part of this and the closing part of last year there had been a considerable increase in the cases of certain of the epidemic diseases, so that in the present year the number of letters issued had more than doubled. The fact, for reasons which will be explained in another part of this report, led to an inquiry further back, when it transpired, from an analysis of the cases treated in the past five years, that the increase of sickness was due to four epidemic diseases—scarlet fever, measles, whooping-cough, and typhoid. In preceding years the number of these diseases had been exceedingly low. From July, 1878, to June, 1879, there were only 55 cases of scarlet fever, 168 of measles, 174 of whooping-cough, and 35 of typhoid; total, 432 cases. From July, 1879, to June, 1880, there was an increase in the number of all these diseases except typhoid, which had fallen to 7, the total being 655. From July, 1880, to June, 1881, there was a decrease in the numbers, the total being 460. But in the latter part of 1881 there was an outbreak of them all of a very extended character, which culminated in the first six months of 1882, so that in this last-named period there were 305 cases of scarlet fever, 574 of measles, 370 of whooping-cough, and 86 of typhoid, yielding a total of 1335. Fifty-five of the typhoid cases were in the northern district, in which the disease was distributed.

Of the other epidemic diseases treated in the dispensary the numbers have been moderate, and very small in respect to some of great moment. For three years, 1877-80, small-pox was absent altogether. In 1880-81 there were 9 cases; in 1882, up to the end of June, 1 case, average, 2 per year. Of diphtheria and croup, the numbers from 1877 to 1882 averaged 6·6 per year; of erysipelas, 27; of pyæmia, 1; of typhus, 0·2, or one case only in the five years. Considering that the practice of the dispensary represents practice amongst the poorest of the poor; that it is carried on in the homes of the poor, in which there is no accommodation for separation of the sick, even when the disease is of the most contagious type; that medical skill is scarcely sustained at all by competent nursing; and that proper food and the proper means of cooking what food there is in an efficient and cleanly manner can rarely, if ever, be supplied, I do not consider that the dispensary represents anything peculiar in regard to the kind of disease to which it administers relief, or to the number of cases of epidemic disease. I shall deal with this subject in another section, but, speaking in this section of the present health of Brighton, the evidence taken at the dispensary shows, generally, a healthy condition of the town in all the poorer districts.

The Sanatorium, which has recently been erected at Bear-hill, comprises two houses for the reception of patients who are suffering from contagious diseases, and is constructed on excellent principles. One of the houses is smaller and older than the other. The newest building, which I carefully inspected, is fitted to take in fifty patients on each side. The wards are spacious, giving from two to three thousand cubic feet of space to each bed. The ventilation is free, and the principle of warming promises well. The position of the Sanatorium, on an elevation which exposes it to the air from the open country as well as from the sea, is well chosen in respect to purity of air, the only difficulty connected with it being the transit of the sick from the town to it. This is met by an ambulance, which is fitted with all modern contrivances. There are in the institution good facilities for the disinfection and cleansing of clothing and bedding, and owing to its surroundings the place cannot be approached, within a

considerable distance, by houses or other buildings. The new Sanatorium is constructed of iron on its outside, lined inside with wood inner felted, and, very wisely, is so framed that it could be taken down altogether and rebuilt at any time at a small expense. It would be perfect in construction if the inner walls were lined with flat galvanised iron, so as to admit of being regularly cleaned by a fire brush. I anticipate that the Sanatorium will greatly relieve Brighton of infection amongst its poor. There were no cases of disease in the new Sanatorium at the time of my visit, the building being incomplete. The older and adjacent building, which contains two wards, each capable of holding twenty beds, is built of wood; there were sixteen cases of infectious disease, chiefly of scarlet fever, in its wards on the day I was there.

The summary of results from the inspection of the medical institutions of Brighton, like that derived from the schools and public charities, is to the effect that the health of Brighton is at this time exceptionally good.

In 1864 I found in Brighton a workhouse situated on Church-hill, in the western portion of the town. The house had been erected in 1820. I was not sparing of it. I described it as "crowded, squalid, dark, worse than a prison," and my advice then tendered was "down with it! For the sake of Brighton as an advanced town, down with it at once. That is the only remedy." The remedy has been applied, and now on the summit of Elm-grove stands a really model workhouse, with its infirmaries and all other necessary accessories. I inspected the workhouse throughout, and have no observation to make upon it, except that its sanitary condition is up to the standard of modern requirements in all respects. There was not a case of infectious disease of any kind within it, and the inmates, old and young, bore as healthy an appearance as ever obtains in a workhouse population. There had been, I learned, a few cases of measles in the infirmary, before last Easter, but since the erection of the building the occurrence of epidemic affections of every kind has been altogether exceptional.

The Parochial Industrial Schools, situated across the Downs, about three miles from Brighton, and containing the children from the workhouse, were also inspected. I found these schools in the best sanitary condition, and, indeed, I remember nowhere to have seen anything of the kind so good in every detail. The children bear evidence of rude health, and the boys, who have a splendid band amongst themselves, excel in musical art. There was not a case of sickness either amongst the boys or girls, at the time of my visit, nor has there at any time been any prevailing epidemic.

Extending my inquiry in relation to the diseases present in those who are under parochial relief, I received reports from the parochial medical officers of the cases under treatment by them in their respective districts. All the districts were free from any spreading or prevailing epidemic. Mr. Leigh, of the central district or parish of Brighton, was good enough to look up his register of cases for me, and reported that from January 1st, 1881, to June 30th, 1882, he had had no case of diphtheria, 7 of typhoid—4 doubtful—38 of measles, 18 of scarlatina—4 doubtful—and 13 of small-pox. Amongst his private patients he had had no case of diphtheria or small-pox, and few of typhoid, but a good many of scarlatina.

The summary of the results of inquiries into parochial medical practice entirely confirms the view indicated from the other institutions, that the present health of Brighton is good, and that there is no prevailing disease of an extensive or serious character.

I turned from the inmates of the parochial institutions to the Police Force, in order to ascertain if there were indications of diseases of an epidemic and serious nature amongst its members. The health of the Police Force affords a fair test of the salubrity or insalubrity of the district or locality in which it is placed. The men constituting the Force are on duty in their respective stations, whether the stations be exposed to the influence of infection or not. They are in like manner exposed to whatever emanations may be given out in the streets, alleys, and houses they guard. They are exposed to these dangers by night as well as by day, and they are, at the same time, exposed to all the vicissitudes of season. In Brighton the Force, numbering from 115 to 130 men, are, most of any persons, exposed, therefore, to such local dangers as may be present. At my visit I found from Mr. Rogers, the surgeon to the police, that he had not an instance of epidemic disease on his list, and that he had

never had such during the period of years in which he had held office. I failed also to obtain evidence that there ever had been such an occurrence since the establishment of the present Force, twenty-eight years ago.

The results of the inquiry and inspection as to the health of the Police Force confirm, in the most signal manner, the previous results.

In the course of making the inspections particularly named in the above passages, I lost no opportunity that offered of prosecuting general inquiries into the health of the inmates of hotels, boarding-houses, lodging-houses, and private houses, and, as will appear in a future page, I made a special inspection of the common lodging-houses. I consulted also many of my medical brethren in large practice in the town as to its present state of healthiness. I met, throughout, with but one statement—namely, that there was no special prevailing disease, and that the amount of disease altogether was so small there was, according to the medical expression, "nothing doing."

In this inquiry, nevertheless, I heard of some instances of serious contagious disease which ought to be noticed. I was informed of a case of diphtheria, but, on looking into it, I discovered that the sufferer had been brought to Brighton, with the disease, in the hope that the sea air would give the only chance of cure. I was informed of two cases of scarlet fever, both of which had been sent to Brighton, with the affection to pass through it there. I was informed of another case where a patient who was recovering from scarlet fever, had come to Brighton, as soon as he could be removed, for the sake of quick recovery. These examples were interruptions to the general statement of the freedom from contagious maladies; but they did not affect the town on the question of its own salubrity. On the whole the investigation yielded the same results as those rendered in the preceding summaries.

As throwing still further light on the subject now in hand, I obtained from Miss Clements, the superintendent, an account of the nurses supplied, under her direction, by the London and Brighton Nurses' Association, situated in Middle-street, King's-road. In the past year and a half this Association has supplied 270 nurses to visitors and families, chiefly to visitors. Of these 15 were employed for infectious cases, measles, scarlet fever, one case of small-pox at Shoreham, one of diphtheria, and one of typhoid. The rest, Miss Clements reports, "were purely medical and surgical cases, mostly invalids sent to Brighton as a last hope."

In reciting the existing conditions of health in the private and public schools; in the large and small charitable institutions for the relief of the sick; in the centres for parochial relief, with the districts through which parochial medical relief is distributed; in the police force; in the common lodging-houses; and in the town generally, I have exhausted all the available, and, as far as I can see, all the possible sources of information. The conclusions I have therefrom arrived at, as to the present state of Brighton, are as follow:—

1. That there is no specially prevailing epidemic or contagious disease in the town or district.
2. That there is nothing whatever to point to any extant local cause as producing such diseases.
3. That the health of the town, considering its size, the special dangers to which it is exposed as the convalescent resort and sanatorium of London, and its position as a refuge from London of vast numbers of unhealthy poor itinerants, who come to minister to the service and amusement of visitors, is unusually good.

#### HEALTH OF BRIGHTON IN THE RECENT PAST.

The present health of Brighton may be accepted as extremely good, and, so far, my inquiries have borne the most satisfactory fruit. I have now to enter on a new field, and to ask, Has the same condition been maintained in the recent past? It is presumed by some that this has not been the case. I have therefore taken the utmost pains to ascertain the precise facts.

The question before us resolves itself immediately into one relating to the presence or absence of the zymotic or contagious diseases. There is no suspicion that the healthiness of Brighton has in any way failed in regard to its climatic healthiness. It is not assumed for a moment that there has been an increase of bad health from what are known as constitutional or diathetic affections. It is not assumed that those diseases which arise from strictly malarious causes, diseases of the type of ague, which were once so

prevalent in Brighton, have revisited Brighton. On the contrary, it is well understood that ague, which I still found lingering in the place in 1864, has now disappeared altogether, unless it be imported.

But it has been assumed that the zymotic or contagious affections have been on the increase, and that they have taken permanent hold owing to the existence of certain sanitary defects on which they are supposed to thrive. To the investigation into the truth of this allegation I have specially directed my inquiries.

My first efforts in this line of research were made to determine how matters really stood on the official tables of mortality. Putting aside all mere general reports and rumours, I went to the prime source of information, the records of the Registrar-General, and that the facts made put forward in all their truthfulness I introduce them as they have been supplied from the Registrar-General himself, first to Mr. J. R. Hollond, M.P., for the Mayor, and through him to me.

"General Register Office, Somerset House.

"In the ten years 1871-80 the mortality from what are ordinarily called the seven zymotic diseases was lower in Brighton than in any other one of the twenty towns, of which weekly statistics are published by this office.

"The mean annual rates of mortality per 1000 from those diseases, collectively and singly, were as follows:—

TABLE A.

	1871-80.		1881.	
	20 Towns.	Brighton.	20 Towns.	Brighton.
Small-pox . . . .	0.42	0.09	0.32	0.08
Measles . . . . .	0.51	0.27	0.55	0.19
Scarlet fever . . .	0.80	0.39	0.66	0.70
Diphtheria . . . .	0.11	0.08	0.15	0.06
Whooping-cough . .	0.76	0.45	0.57	0.31
Typhoid fever . . .	0.50	0.24	0.31	0.40
Diarrhoea . . . . .	1.22	1.00	0.80	0.45
The seven above-mentioned diseases }	4.32	2.52	3.36	2.18
All causes . . . .	21.8	20.4	21.7	19.0

"In 1881 the zymotic death-rate, as a whole, was also much lower in Brighton than in the twenty towns collectively; but in one of the seven diseases—namely, fever, and in this one alone—the mortality in Brighton was above the general average of the twenty towns (see Table A).

"In 1882 the state of things has been very different. In the first and second quarters of this year the zymotic death-rate has been almost twice as high in Brighton as in the twenty-eight greatest towns, taken collectively, owing to the excessive mortality from measles, scarlet fever, and whooping-cough (see Table B).

TABLE B.

	FIRST QUARTER, 1882.		SECOND QUARTER, 1882.	
	28 Towns.	Brighton.	28 Towns.	Brighton.
Small-pox . . . .	0.13	0.15	0.10	0.00
Measles . . . . .	0.85	3.04	0.36	2.01
Scarlet fever . . .	0.56	1.76	0.44	1.10
Diphtheria . . . .	0.18	0.07	0.15	0.15
Whooping-cough . .	1.47	2.89	1.13	1.25
Fever . . . . .	0.33	0.15	0.29	0.15
Diarrhoea . . . . .	0.24	0.11	0.34	0.21
The seven above-mentioned diseases }	3.76	8.17	3.31	4.87
All causes . . . .	24.7	29.2	20.9	21.8

The study of this instructive table affords a complete exposition of all that can be said to the detriment of Brighton, and if the facts I have put forward in respect to the prevalence of disease in the public and medical institutions of Brighton be re-read by the side of this table, they will be found to tally with it, the total of the result being, that at the close of last year, and in the first two quarters

of this year, the town was visited by epidemics of four diseases of fatal character, from which, for many years past, it was comparatively exempt when placed in comparison with the average mortalities of twenty towns containing, like itself, a large population. On referring to the table A, it will be seen that for ten years Brighton stood as 0.27 instead of 0.51 in relation to measles; as 0.39 instead of 0.80, less than half, in relation to scarlet fever; as 0.45 instead of 0.76 in relation to whooping-cough; and as 0.24 instead of 0.50 in relation to fever, when compared with the average collected from twenty towns. On summing up the totals from these four diseases it will be seen that Brighton stood as yielding from them a mortality of 1.35 as against 2.57.

In respect to the three other zymotic diseases Brighton retained for the whole period a first position—namely, 1.17 as against 1.75.

In 1881 this same favourable position was held, with the exception of one disease—namely, typhoid fever.

In 1881 the mortality from typhoid took an exceptional rise in Brighton from an average of 0.24 for the preceding ten years to 0.40. In this respect the town compared unfavourably with the nineteen other towns for that year (1881), in which towns the average mortality had, strangely enough, fallen to 0.31, but it still remained favourably placed in regard to this particular disease in the same twenty towns for the ten previous years, the mortality from typhoid in them averaging, collectively, 0.50. In a word, in 1881, the typhoid mortality rose in Brighton from 0.24 to 0.40, while it fell in the other towns from 0.50 to 0.31.

The change here mentioned would have been too small to have affected the question of the past health of Brighton at all, but for the sudden phenomenon of a rapid rise of mortality in the first months of the present year from the three other diseases already named—measles, scarlet fever, and whooping-cough. In the first quarter the mortality from measles was 3.04, and in the second quarter 2.01; scarlet fever was 1.76 in the first, and 1.10 in the second quarter; whooping-cough was 2.89 in the first, and 1.25 in the second quarter; while fever (typhoid) fell to 0.15 in the first, and remained at 0.15 in the second quarter.

I have now stated the facts which have been observed. Condensed, they stand for data as follows:

Brighton, during the years 1871-80, showed a mortality below the collective average mortality of twenty large towns in England, all causes of death being included, in the proportion of 20.4 to 21.8.

Brighton during the same period showed an average of deaths from the principal zymotic diseases of 2.52, in comparison with an average of 4.32 in twenty large towns taken collectively, and the same continued throughout 1881, except in reference to one disease, fever (typhoid), of which in the collective average of the other towns there was a great reduction of mortality, with an increase in Brighton.

In the first half of the present year there was a great increase of mortality in Brighton from three zymotic diseases—namely, measles, scarlet fever, and whooping-cough.

In the first half of the present year the mortality in Brighton from five zymotic diseases—namely, small-pox, diphtheria, croup, diarrhoea and typhoid—was below the average of that in twenty-eight towns taken, collectively, with which it was compared.

With the close of the second quarter of the year 1882 the mortality from the three diseases which had raised the mortality in Brighton began to decline and to approach the former average.

Taking these as the reliable data, let me now explain the reasons for the remarkable change of rate of mortality which has been stated as pertaining to 1881-82 in Brighton.

The primary truth that comes out, and to which all the evidence points, is that the phenomena of disease and mortality, on which stress is laid, occurred from four diseases—namely, typhoid, measles, scarlet fever, and whooping-cough. This is demonstrative, and two views are open for explaining why these diseases should suddenly have broken out with so much intensity.

The first view is an hypothesis. It supposes that the diseases broke out and proved so fatal as to change the rate of mortality in consequence of local causes of insalubrity and impurity of air.

If this hypothesis were true, there must have been discoverable some great local change in the condition of Brighton; some climatic change; some change in regard to the mode of life of the inhabitants; some change by which

the public works of the town were modified or perverted. There has been nothing of the kind discoverable. There has been no unnatural severity of climate; no particular change of life or habit; no change in water-supply; and for eight years no change in the system of removing the sewage.

If this hypothesis were true, the diseases in question ought to have spread through all classes of the community as from a common cause affecting all. The diseases did not spread in that general way; they spread, as I shall show, from special origins and amongst special classes of the population.

If this hypothesis were true, the other zymotic diseases ought to have been equally influenced by the common insalubrity. Small-pox, diphtheria, diarrhoea, ought to have been prevalent beyond the extent of their prevalence in other towns. They were in fact less prevalent.

If this hypothesis were true, five other spreading diseases, not as yet named, ought to have had a prominent place in the mortality returns. I refer to croup, erysipelas, child-bed fever, surgical fever, and typhus. These diseases, as essentially diseases of impure air as the diseases which were present, are conspicuous by their absence. They add so little to the mortality that they are not noticed in the official record.

If this hypothesis were true, it ought to be supported by an easy exposition of the mode in which the persons who suffered were affected by the insalubrious air. It ought to be demonstrated from what particular polluted source of water, or food, or air, the measles, the scarlet fever, the whooping-cough, the typhoid sprang. There is no attempt at such an exposition.

On all these grounds the hypothesis fails to afford the faintest reasonable explanation of the phenomena. It resolves itself into a mere term. It speculates on a common cause for which there is no common reason. It names this cause as sewer gas, while it makes no analysis of such gas to show that the poisons of the particular diseases were in it; offers no shadow of proof that the persons affected were influenced by such gas, and does not indicate why other persons escaped, nor why other poisons of disease were not also in the gas. It does not venture to assume that sewer gas produced any of the diseases named. It does not dare to prove that such gas can produce even one of the diseases, or to specify one so produced.

The second explanation of the phenomena of disease which we have discovered as leading to the change in the mortality of Brighton in the recent past, is based on clear and simple principles. It does not enter into hypothesis, but deals with well-known and obvious facts. It may be stated in the plainest manner, so that anyone who reads it can understand it.

The four diseases, together with the other of their class, called zymotic, demand for their development three conditions:—(1) A person in a state of body that renders it susceptible to, or liable to become affected with, the diseases. (2) The presence of an exciting organic particle that is capable of causing the disease in the susceptible person. (3) Contact of the susceptible person with the exciting organic particle.

There is a dispute amongst the learned regarding the nature of the exciting organic particle, as to whether it be living or dead, and, whether it come from without or from man himself, into which dispute I need not enter here. It is sufficient for our present practical purpose to know that the particle is necessary as a factor in an epidemic outbreak; that, as a rule, to which there are few exceptions, it passes from affected persons; and that, in those who are susceptible to it, it produces disease if it reaches them. The particle is absorbed by the susceptible; it is, as it were, planted in them; and, after a certain definite period, called the period of incubation, it causes in them phenomena or symptoms which are the same as were presented in the person from whom it was derived.

In every town there is a population that is susceptible to the action of these disease-producing particles; but all persons are not equally susceptible, because those who have once been subjected to them are, to a large extent, prevented thereby from becoming affected a second time.

Hence it happens, clearly enough, that young children who have never been subjected to any of the zymotic diseases, but who with very few exceptions are born susceptible to them all, are most liable to take them when infection is carried to them; and hence the facts, so well

known, that the spread and mortality of the diseases of the zymotic type are largely amongst the young.

As a further rule it follows that if in any town a long interval elapses in which the zymotic diseases are absent, time is allowed for the birth and growth of a very large population susceptible to the diseases, in whom an outbreak, if it begin, will spread, and will include unusually large numbers in one epidemical attack.

This is exactly what occurred recently in Brighton. For a long period, extending over eleven years, the town had been free, beyond what is usual, from the diseases which recently were introduced. Its very healthiness, in this respect, was therefore a cause of its susceptibility to an extended outbreak, if an outbreak were once lighted, and this in relation to more than one disease of serious importance.

It happened, unfortunately, that amongst a large and susceptible population four of these diseases broke out in quick succession, three of them almost at the same moment.

I use the word unfortunately in describing these facts, but I might with equal correctness use the word exceptionally, for it is one of the rarest events I know of, in epidemiological records, that these zymotic affections should be introduced, and should extend with almost equal intensity, in the same place and at the same time. The event is a proof in itself of the freedom of the town from the diseases for a long period of time before.

The epidemics, nevertheless, might have occurred in the same simultaneous manner, and never have been commented on, but for an additional influence which was also unfortunately present. The epidemics took place at a time when all the seasonal influences were unfavourable to recovery from the diseases, and so their presence was shown by large but not under the circumstances extraordinarily large mortalities.

It was laid down by the distinguished scholar and physician, Arbuthnot, that every season has its special diseases. The saying is in some measure true, and the prevalences of diseases and of the mortality arising from them may be considered as well marked. In 1853 I made the question of the seasons in relation to diseases and mortality the subject of a special and prolonged study from the Registrar-General's returns, including in the inquiry a minute analysis of 139,318 deaths occurring between 1838 and 1853 from small-pox, measles, scarlet fever, whooping-cough, croup, diarrhoea, dysentery, cholera, influenza, ague, remittent fever, typhus, erysipelas, quinsy, bronchitis, jaundice, and carbuncle. The districts in which the diseases and deaths took place were London, Devon, and Cornwall.

Out of the 139,318 cases thus chronicled as occurring from the above named diseases, the percentage of mortality in the different quarters of the year, estimating the gross mortality according to the season, without reference to particular years, ran as follows:—In January, February, and March, 25 per cent.; in April, May, and June, 21 per cent.; in July, August, and September, 24 per cent.; in October, November, and December, 28 per cent.

Having learned thus much, I set about ascertaining, on the same large scale, whether the fatal diseases were in any way special to the seasons. The answer to the inquiry was to this effect: Whooping-cough, croup, small-pox, and bronchitis are most common in the first quarter; in the second quarter quinsy only stands ahead; in the third quarter, diarrhoea, dysentery, and jaundice take the lead, and in this third quarter also, Asiatic cholera, when epidemic, assumes a greater mortality and prevalence; in the fourth quarter, influenza, ague, remittent fever, typhus, scarlet fever, measles, erysipelas, and carbuncle take the lead.

The tables from which these facts were drawn were published in the *Journal of Public Health* for December, 1855, and they have since been often referred to and confirmed.

The most extensive and latest review of this same subject is by Messrs. Buchan and Mitchell, of the Scottish Meteorological Society, who, in the journal of that Society for 1875, published the results of thirty years' observation on the influence of weather on mortality in this country. Their analysis includes the returns of mortality of England and Wales from 1838 to 1874. From their tables we learn that the four diseases and their complications, which specially concern us at present, have the following history of season and mortality:—

Typhoid shows its maximum death-rate in October and November, extending, with gradual diminution, into Decem-

ber, but not falling below its average until the last week in February. Measles shows its maximum in November, December, and January, while bronchitis, the common follower of measles, attains its maximum in the second week of January, continuing to fall slowly, till the end of March. Scarlet fever has its maximum from the beginning of September until the end of the year, with, for ten years out of the thirty, a high death-rate continued into the year immediately following. Whooping-cough is above the average, in respect to death-rate, from the middle of December until the beginning of June, the maximum being reached in February, March, and first half of April.

The high mortality from these diseases in Brighton, in the latter part of 1881 and first half of 1882, is all in natural

keeping with the facts above stated. The epidemic of typhoid took place at the moment when its mortality is naturally highest. Measles, and the subsequent bronchitis which I found was the chief cause of death, followed the same law. Scarlet fever, which began to rise in the last months of 1881, extended through the first months of 1882 before it declined. Whooping-cough, in steady observance of law, attained its usual maximum in the first four months, and then began to decline in the natural order.

Messrs. Buchan and Mitchell describe these seasonal variations of mortality from disease by what they call a curve, of which I give one illustration, selecting the curve of whooping-cough as that of a disease which is unusually free from variation.

#### CURVE OF MORTALITY OF WHOOPING-COUGH FOR ALL AGES AND BOTH SEXES.

Derived from calculations of thirty-four years.

I would, in passing, suggest that it would be well in Brighton to register, in future, the mortalities from all diseases on a system of curves of this kind. The precise influence of weather on the mortality would thus be retained and would prove of sterling value to the sanitary staff.

The explanation of the increased mortality of Brighton during the time to which reference is now made, is easily and clearly understandable. The diseases causing the mortality came and went away. They did not depend, obviously, on any general cause located specially in the town. They were produced by contact of the susceptible unaffected with some who were affected.

All towns, all houses even, are open to the risk of receiving infection, and amongst the most healthily regulated towns and households some contagious diseases will spread if the residents be susceptible to the action of the contagion. Scarlet fever, measles, and whooping-cough are diseases particularly easy of distribution from person to person in a susceptible population, and Brighton is inoculated, from without, by these diseases from without many times year. It would be ever under their spell if it had a population always on hand that was unprotected by previous attacks. Sometimes it will have such an unprotected population, and then, as it is no more invulnerable than other places, it will be subject to an epidemic.

All towns are exposed to epidemics from what may be called accident in the mode of distribution of the agent which lights up the spreading disease, and this particularly when the agent can be conveyed or carried wholesale in articles of food or clothing. From this accident Brighton is no more exempt than the rest of the towns of the United Kingdom, and to this last-named cause it has been subjected, as well as to the former causes to which I have adverted.

The disease called typhoid fever is one of those affections which can be conveyed extensively by food and drink, in any community, after the accident of its introduction and during ignorance of danger. The organic exciting particle or poison of typhoid is usually, and as many think always, conveyed by fluids taken into the body as drink. The poison may, possibly, be conveyed for a short distance by the air, but so little is this event feared that in some hospitals for the sick typhoid patients are allowed to remain in the general wards separated from the other patients by the mere distance of one bed from another. If, by accident, the excretions from the typhoid patient were to find their way into the water or milk or other uncooked food or drink supplied to the other patients, the outbreak of typhoid would be certain and general, however pure and good might be the surrounding air. But under less exposure to danger no evil need accrue.

The town of Brighton, then, like other towns, is liable to these two risks. It may be infected with some spreading diseases by the communication of the exciting causes of these diseases from person to person; or by the accidental distribution of the cause to many persons through substances

passing as foods or drinks, after being exposed to contamination. It was in these two distinct ways that Brighton in the recent past was subjected to the four diseases which led for a brief period to an exceptional increase of mortality.

The epidemics of measles, scarlet fever, and whooping-cough were so obviously the result of spreading by personal contact that no one on the spot who watched their progress doubted the fact for a moment. It was the young children in the poorer neighbourhoods who suffered most severely. It was by a case brought into a school or a family that the mischief was introduced. The schools and families that were most isolated from the infected escaped. The epidemic of measles was not itself malignant, but it caused in many instances severe bronchitis. The epidemic of scarlet fever was not generally of the malignant type, but in densely populated parts it spread rapidly from one child to another. The epidemic of whooping-cough was similarly disseminated, and I heard of instances in which the three diseases—measles, scarlet fever, whooping-cough—followed each other in the same family. In a number of cases children just recovered from measles contracted whooping-cough. The mortality was chiefly amongst the poor, and, indeed, hardly reached any other class. The children of the Circus-street Board School for girls and infants—a school where the parents of the children are very poor—were affected by the three diseases almost in instant succession, and yielded no less than eighteen deaths. In this there is no reason for surprise, for in many cases three or four families of the infected lived in one house. They were badly clad, and some actually had no bed. I saw one of these children who, during the epidemic season, suffered, with his brothers and sisters, from measles. Their father was an industrious man but disabled, partly, from work; their mother had to go out to work. They were accustomed to come to the school scantily clothed and fed. One of them caught measles from another child, and the rest followed in turn. A lady who visited them at their home, and who was my informant of the facts, found four of them huddled together in a large chair, and in that position one died.

In the Richmond-street Schools measles, scarlet fever, and whooping-cough spread in the same way, by personal contagion, and at one time 100 children were away from school, fourteen, under the age of five, dying from these illnesses. These were mostly children badly housed, clothed, and fed, their poor parents not having means sufficient to provide the care and attention demanded. One boy sickening with scarlet fever in the school could not be taken home for a long time because the mother was out at work at a distance. In the end a little sister, who had not had the disease, fetched him home, and became herself another victim. In the St. John's and Hanover-terrace Schools the epidemics spread in like manner, St. John's yielding twelve and Hanover-terrace four deaths from amongst their scholars.

It is unnecessary to enter into further details in respect to the mortality from the late epidemics of measles, scarlet

fever, and whooping-cough. They were dependent in no way on any special agent, like sewer gas, or other cause of a general kind, affecting the air of Brighton. They depended on the natural development, in a susceptible community, of three contagious diseases, occurring in poor and overcrowded localities, at a period of the year when these diseases are always most fatal. They depended for their unusual diffusion on the unusual coincidence that these diseases had for a long time been in abeyance, and were accidentally lighted up all at one time. In any town in the kingdom the same results would occur under the same circumstances, according to our present knowledge, and they will continue to occur until the day arrives when there shall be no poverty and no exposure of the young to those who have contracted contagious diseases; a time, that is to say, when the poorest children of Brighton shall be as well placed as those other school children also there, who, as I have shown in the first section of this report, escaped so remarkably.

The outbreak of typhoid fever in the latter part of last year was accidental in respect to distribution. All the evidence obtainable points in that direction, and is as near to proof as such evidence can be, while there is no other evidence of any kind to explain the outbreak. The facts, in short, are these. In the third week of September last there was a case of typhoid in the Lewes-road, which was quickly followed by other cases. Very soon the suggestion was made that the attacked were persons who had partaken of milk from a certain dairy supply in the Lewes-road. The suspicion was not at all surprising, because it originated from facts of common observation. One gentleman, who lost a child from the epidemic, gives me, for instance, the following report. His son and four of his daughters being in Lewes-road in the third week of September, went into the dairy or milk shop referred to, where the son and three of the daughters drank of the milk supplied. All those who partook of the milk began to sicken towards the close of the following week, and were found by Dr. Stephens to have typhoid fever, from which one died. The one who did not partake of the milk did not suffer. Here there were five evidences in proof of the source of infection—(1) That four persons who were subjected to the same possible source of infection were all affected. (2) That the affected fell ill at the same time, proving exposure at the same time to the same producing cause. (3) That the first appearance of symptoms ending in typhoid, calculated by the natural period of incubation of typhoid, from nine to twelve days, points to the date when the milk was taken as the date of infection. (4) That the one who was not subjected to the possible source of infection was not affected. (5) That there was at the time, in the house at which the milk was drunk, a case of typhoid. Since the period when the outbreak of cholera in London was traced so circumstantially to the water of the pump in Broad-street, Golden-square, there has been no more conclusive evidence given of a local source of infection of a spreading disease.

The theory of the origin of the outbreak from the centre I have named was soon under the observation of your medical officer of health, Dr. Taaffe, and of your analyst, Mr. Moore, who added to facts similar to those I have just recorded further valuable evidence, which was reported by Dr. Taaffe to the Sanitary Committee, and which I may here summarise under four short heads—

1. That milk taken from the dairy in question on Sept. 28th had in it 20 per cent. of water that had been added to it, and that such water was foul or contaminated, the milk being of bad odour, undergoing rapid lactic acid fermentation, and yielding a cream which at 80° F. developed fungoid growths; a milk evidently unfitted for consumption.

2. That there was a source or sources on the premises of the suspected shop from which the contaminated water could have been obtained, the water of the premises being held in two cisterns, each over a water-closet, and that the water from one of these was contaminated, showing '08 of free ammonia per million, '23 of albuminoid ammonia, a deposit of wheat starch, confervoid aggregated corpuscular bodies, and some monads.

3. That of 91 families who drank of milk supplied from this source, 26, or 1 in 3·5, were attacked by typhoid, all the persons falling ill about the same date.

4. That of 696 families in the neighbourhood supplied from other dairies, only 27 (1 in 25·7) were attacked, and

that all these cases, with two exceptions, which occurred about the 22nd to the 24th of September, happened subsequently to the end of September.

Putting all these facts together, and coupling with them the further fact that the carekeeper of the suspected house in Lewes-road was suffering from typhoid on September 22nd, from which date the epidemic dates, Dr. Taaffe reported to the Sanitary Committee his opinion that this epidemic of typhoid was due to a local cause—namely, to water contaminated from a closet or from closets of a house from which milk was supplied, and with which such water had been admixed.

I confirm this conclusion on every point. Without the least strain it explains all the mystery, and while it relieves the town, as a corporate body, from responsibility, it is an intimation to all individuals who supply vital public wants of the responsibilities which rest upon them if they fail, from any cause, to avail themselves of the advantages of a sanitary kind which are placed at their disposal, or evade the rules which are laid down by the common consent of elected authorities for the common good.

The municipality of Brighton can no more than that of any other town be held responsible for individual error in respect to distribution of disease. It might as justly be held responsible for the distribution of fire. It can concert general measures and offer counsels against the origination and spread of disease and of fire; it can appoint inspectors to see to the state of buildings; it can provide a skilled sanitary officer or captain to stamp out disease or fire; it can provide an ambulance or a fire escape; it can provide a hospital for those who are injured by disease or by fire. But it can no more be expected to look after every man's water-closet and water-cistern than after the turning out of his gas at night or the safety of his lucifer match-box.

Taking all the facts into consideration, I have to report that, with the exceptional occurrence of four fatal contagious diseases occurring between the 22nd of September last and the close of the second half of the present year, the health of Brighton for many years past has been unusually good and free from epidemic disease. I have further to report that the mortality from four diseases in the epidemic period defined was due to accidental and social, as distinguished from any general causes affecting the town altogether, and that the town has been singularly favoured in respect to the prevalence of the other diseases of the contagious and epidemic type.

#### THE WATER-SUPPLY OF BRIGHTON.

In 1864 the water-supply of Brighton was reported on by me as "unlimited and pure." I have nothing to add to that statement, and nothing to take away.

There are two sources of supply: one from the Goldstone, the other from the Lewes-road Works. I have had the opportunity at the Goldstone Works of descending to the sources of supply, and of seeing the water as it is laid up in the huge reservoirs in the chalk from which it is pumped and supplied to the town. The Lewes-road supply differs little in character from the Goldstone, and both are excellent. The waters were reported upon by Professor Frankland in March last; but, in order to make this report complete up to the latest time, I took specimens of both waters from the supplies on Saturday, July 8th, and submitted them for analysis to Mr. Wynter Blyth, the author of the admirable practical work on "Foods, their Composition and Analysis."

Mr. Blyth's report is herewith subjoined.

"Department of Medical Officer of Health,  
Court House, St. Marylebone, W.,  
July 15th, 1882.

"I beg to submit a report of the result of my analysis of the Brighton water. The values of the analyses, conducted on the usual principles, are thrown into the annexed table, so that they may be compared with the analyses made by Dr. Frankland in March, 1882.

#### No. 1. Main pipe, Goldstone Works.

"This water was perfectly bright, clear, and palatable; no sediment was deposited on standing, and a microscopical examination indicated entire freedom from any impurity detectable by the microscope. The chemical data show that there is an entire absence of free ammonia; low values for carbon and nitrogen; and just sufficient hardness to give a

pleasant taste. The saline matters in the Goldstone water may be expressed in grains per gallon, as follows:—

Carbonate of lime	12·880
Carbonate of magnesia, with some nitrate and a minute quantity of sulphate	5·087
Chloride of sodium	3·290
	21·257

"The amount of carbonates of lime and magnesia that the water holds in solution depends mainly on its content of carbonic acid gas, and therefore varies at different times of the year; nevertheless, the "hardness" and the total solids in the March analysis very fairly agree with the figures in the July analysis. The value of such a supply of water of a constant composition is great.

"No. 2. Lewes-road.

"This water was found equally clear and palatable. The difference in composition between the two waters is unimportant.

A gallon of No. 2 contains the following saline constituents:—

	Gr.
Carbonate of lime	13·44
Carbonate of magnesia, with some nitrate and a trace of sulphate	5·46
Chloride of sodium	3·62
	22·52

"No 2, like No. 1, is free from any impurity.

As a whole the water-supply of Brighton is of a first-class character, and it is one of the purest waters of its kind I have ever examined.

*Result of Analysis of Brighton Waters expressed in parts per 100,000, by Mr. Wynter Blyth.*

A.D. 1882.	Total Solid Matters.	Organic Carbon.	Organic Nitrogen.	Ammonia.	Nitrogen as Nitrates & Nitrites.	Total Combined Nitrogen.	Previous Sewage Contamination.	Chlorine.	Hardness.		
									Temporary.	Permanent.	Total.
No. 1.—Goldstone, July .....	27·57	150	050	...	500	650	...	2·8	12·1	7·3	19·4
Ditto, March (Dr. Frankland's Anal.)	24·80	148	054	...	450	504	...	2·8	12·4	7·0	19·4
No. 2.—Lewes-road, July .....	32·4	170	080	...	445	484	...	3·1	14·7	7·7	22·4
Ditto, March (Dr. Frankland's Anal.)	27·00	126	030	...	435	474	...	3·0	12·8	7·5	20·3

(Signed) A. WYNTER BLYTH."

The report of Mr. Blyth sufficiently describes the state of the Brighton water at this time, and as there is no prime source from which the water can be contaminated, it may be accepted as one of the purest supplies, as well as one of the most unlimited.

Like all waters derived from the chalk it is naturally a hard water, but, as the mayor pointed out in his paper at the late Health Congress, it can be softened by a very simple domestic process. From the nature of the supply it is only from the most culpable negligence that the Brighton water can be made a medium for the conveyance of disease.

In every house the water can be laid on in constant supply, and there is no occasion for an intermittent supply anywhere. Gradually, throughout the town the constant supply is being laid on, and, when that is universal, such an accident as the spread of typhoid through milk charged with water from an impure cistern will be practically impossible.

The system of hydrants possessed by the town by which water, used for extinguishing fire, can be carried to any required height without an engine, is much to be commended. No town in the kingdom is, I think, so well provided for in this respect as Brighton.

#### THE SEWERAGE AND DRAINAGE OF BRIGHTON.

I come now to one of the most important parts of my report, the sewerage and the drainage of the town of

Brighton. In approaching this subject I desire to make two distinct statements.

1. All through my career as a sanitarian I have been a consistent advocate of the separate system of drainage and sewerage; I have contended, and, far from altering my opinion, I am the more inclined to contend for it every day, that for a town to be scientifically and perfectly drained two conditions are necessary: (a) That the sewage from the houses be conveyed away by its own separate system, with a sufficiency of water to carry it equally on all occasions, and perfect flow at all times to ensure its delivery, whatever may be its ultimate destination, to the land or the sea. (b) That the rain or storm water should be separately disposed of. In Brighton this system is not carried out, and if I had had a voice in the system that was adopted prior to 1871, I should have been the most strenuous of those who would have declared for it. Mr. Edwin Chadwick, who has been so devoted to the advocacy of this separate system, would not have been more earnest than I should have been in its favour.

2. But while stating this position, in the strongest manner, as the one I personally take, I am bound in honesty to admit that I can discover in Brighton no evidence of disease as originating from the system which has been adopted, and which lets the storm water and the sewage commingle and escape by a common intercepting canal and outlet. On the contrary, I am forced to the conclusion, from the weight of the evidence before me, that the facts derivable from an unprejudiced study of the records of disease and the causes, are as favourable to the present system, so far, as I could have expected from that which I should always advise and prefer.

The dangers presumed to be attendant on the present system are that the large sewers which are necessary to carry the two supplies, sewage water and storm water, have to be freely ventilated so as to allow the gases which emanate from the sewage to escape into the air. If this be not done, it is assumed that the sewer gas will escape back into the houses and contaminate them.

Again, it is assumed that when the sewers are ventilated in their main lines, the ventilators being in the roads beneath which the sewers are laid, there is an escape of sewer gas into the streets; and that when the streets run in ascents, as at Brighton, the gas rises to the higher levels and finds escape there with special freedom, and this particularly when the main exit for the sewer is tidelocked and there is an accumulation of sewage in the intercepting canal.

The hypothesis, if it be true in a physical sense, is not sustained by the results of disease as they are manifested at Brighton.

The precise relations of sewer gas to disease are as yet indifferently understood, very few observations having been on the subject. The late Dr. Barker, of Bedford, who made one of the best researches that has ever been conducted on the effects of sewer air, concluded that cesspool and sewer emanations, when they are steadily inhaled, are poisonous, the symptoms of disease induced being those of intestinal derangement, followed by prostration, increased temperature of the body, distaste for food, and those general signs which mark the milder forms of continued fever common to the dirty, ill-ventilated homes of the lower classes of the community.

It has been more recently indicated, from experience, that the fever which follows childbirth is sometimes induced by sewer air. It has also been indicated that typhus, surgical fever, erysipelas, and diphtheria may be produced by the inhalation of sewer gas.

If these inferences be true, then Brighton is singularly free from the effects of sewer air. Typhus is practically unknown in Brighton; that continued fever which Dr. Barker describes is in no return that I can find, and if it be in any I have not seen it must be extremely rare; childbed fever is also most uncommon; and surgical fever is equally so; erysipelas is comparatively rare.

Diphtheria, which some have assumed to occur from sewer gas, is very rare. From 1871 to 1881 the mortality from it was lower in Brighton than in nineteen other large towns on the average computation. In the first quarter of this year the mortality from it in Brighton was 0·07 to 0·18 in the other towns. In the second quarter of this year only has it come up to the average, and in respect to three of the cases that helped to raise the mortality from it in the second quarter the facts are specially peculiar. In one case the child was brought into the town with the affection from

London, in the hope that the sea air might cure it. In the second case, as I found from the report of the physician in attendance, the child sickened on the second day after arrival in the town, which, giving only seventy-two hours for incubation, excludes Brighton as the centre of infection, or, at least, renders it very improbable. The third case was one which, if of local origin, was so complicated in respect to origin that no clear evidence of an explanatory kind could be obtained. The patient, in wet clothes, sat in a crowded miscellaneous assembly at the Aquarium before being seized with the disease. She was believed to have been exposed to a bad odour from the ventilator of a sewer, but I found the most contradictory statements as to the character of the odour, and even as to the existence or non-existence of an odour or emanation of any kind. Further, although I was informed that five cases of sore-throat had occurred some weeks before in the same house, and recovered, I could trace no other case of diphtheria in any other house near to the ventilator, though some were nearer to it than the house in which the case occurred. Lastly, I could get really no satisfactory proof that the affected child had been exposed to any emanations from the ventilator. I have seen so many cases of diphtheria, in children predisposed to the disease, coming on from cold, after exposure to fatigue and wet, without any suspicion of exposure to sewer air, that I dare not, for my part, accept in this case the hypothesis of contraction of the disease from inhaling sewer gas, unless I was sure of these primary facts. Firstly, that the child did inhale sewer air. Secondly, that the contents of the sewer air had been charged from another case with the specific poisonous organic particle. Thirdly, that the period of incubation of the disease was in accordance with the period of inhalation of the poison. Fourthly, that other persons equally exposed were also affected. In the case in question, not one of these facts was forthcoming or obtainable.

I repeat, then, that while the system of disposal of sewage at Brighton is not the one I should have suggested, I have found no evidence whatever that the sewage has proved a source of zymotic disease. On the contrary, I am forced to the conclusion that the zymotic diseases which might be attributed to sewer gas have been less fatal in Brighton than in the other towns of equal size for many years past, and singularly so during the time that the present system has been in operation.

On the question of the condition of the sewers and drainage system of Brighton, as it is at present, I have used every endeavour to become thoroughly and practically acquainted.

I entered the main or intercepting sewer of the town at every available part. I traversed it for several hundred yards. I noted its outfall, its construction, and the points where it received its tributaries. I also made observation on the force of the air that passes through it. I inspected, as far as possible, the main sewers leading into the intercepting sewer, the sewers leading from the streets into the mains, the drains leading into the street sewers, the manholes leading down into the sewers, and the sewer ventilators. I went at various times of the day, and late into the night, to the ventilators in different parts of the town, to notice if there were emanations from them; and, accompanied by Mr. Lockwood and his staff, I took part in the process of flushing the sewers with water through the manholes, in several parts of the town.

My inspection of the intercepting sewer commenced at the outfall at Portobello, four miles to the east of Kemp Town, at a time when, the tide being low, the contents of the sewer were being discharged into the sea. The outflow gave abundant evidence of discharge of recent sewage from the town, and the penstocks and gates at the outfall were all in good working order. Proceeding towards the town on the sea side, in the line of the sewer, I entered it again at Roedean, where I found valves placed across it which opened in the direction of Portobello, to let sewage and air pass on, but which prevented them from passing back towards the town. The valves were in efficient working order. I found here also a furnace and shaft, which had the effect of drawing off, from the part of the sewer which lies towards the town, some seven thousand cubic feet of air per minute. The air passes over the flames of the large furnace and escapes afterwards by the tall shaft. I next followed the sewer from Black Rock to the Steyne, where I entered it to inspect the discharges of the main from the northern and Marine Parade sewers and the catchpit in the Steyne valley. I took readings here again of the air currents, and I walked through

the sewer back to the Chain Pier. I next followed the sewer to its commencement at the western end of Hove and entered it again there.

From Hove to the Steyne the sewer is five to six feet in diameter, gradually increasing in size to seven feet at the Steyne, and retaining that size during the further part of its course. It is well built, and cannot, I think, permit leakage. Mr. Lockwood supplied me with the measurements, with the height of the invert at Hove, one foot six inches above high water at spring tide, and of the invert at Portobello—viz., the low level of low water at spring tide. He also gave me the measurements of the fall—namely, three feet per mile; and the rate of flow—namely, one and one-third to one and a half miles per hour. In the length of Hove the sewer receives thirty house drains directly, and eleven or twelve sewers. From the Aquarium there are three outfalls into the sewer; they are flapped on the sewer side, and the flaps are in very good order. At the Steyne the main valley sewer joins the intercepting sewer, and there is a large storm overflow at this point. The sewage of the part of the town lying to the east of the County Hospital enters at Black Rock, and there is another storm overflow at that point.

The air of the intercepting sewer is much less offensive than would be expected. At the time of my inspection the odour of paraffin prevailed over everything, and I learned from the men that this was usually the case. The insoluble paraffin, residue of lamps, passes into the sewer, floats on the surface of the sewage, and gives out its characteristic smell. The sewage was from fifteen to eighteen inches deep in the sewer at the point where I traversed it, between the Steyne and the Chain Pier. It decreased towards the west, and at Hove was not more than from nine to twelve inches in depth. There was very little solid matter under foot. At one place, a little distance from the catchpit in the valley of the Steyne, there was a little accumulation of silt, which had been carried from the catchpit probably before the emptying of the pit in the morning. The masonry of the sewer is of brick, well laid, and seemed to be good in every part. I ascertained from Mr. Lockwood, in respect to the proportion of storm and town water to sewage, that the sewage in dry weather varies from 6 in. to 15 in. in depth, or from about 200 to 500 cubic feet per minute; and that the sewer, when fully charged with rain-water, discharges 8000 cubic feet per minute. About thirty gallons of water per head of the population of Brighton and Hove finds its way into the sewer, or 600,000 cubic feet, equalling 3,750,000 gallons per day of twenty-four hours; but in dry seasons this is increased by special flushing. During the time of my inspection in July nearly 100 tons, or about 23,000 gallons, of water were passed into the sewers in a day for flushing them. Twice in the twenty-four hours of each day the sewage of the town is locked up in the intercepting sewer in consequence of the rising of the tide, the time during which this locking occurs being rather more than half the full day. It is calculated that the capacity of the intercepting sewer is such that it would hold, during the periods when it is tidelocked, more than twice the amount which it receives from the town in dry weather.

I should add to this account of the intercepting sewer that I experienced no ill effects from being so long in it while making my inspection, and that since it has been in use none of the surveyors or inspectors have ever suffered from inhaling the air within it.

During the period of my inquiries I received many communications respecting the emanations of bad odours from the ventilators in the streets. This led me to visit the reported places at different hours. I found, in the same way as is found in London, that sometimes there was a sewer smell, never intense and not always present. In the supposed worst cases of which I was informed the evil turned out to be due entirely to different causes. In the most offensive instance of all the cause of the stench proved to be an escape of gas into the earth in a narrow street; the ventilator was quite free of odour. In another instance the offence attributed to a ventilator was from dead animal matter cast into a heap near the ventilator. In a third instance it was from dead sea-weed. In some other instances the cause seemed to me to be different, and to be due to neglect on the part of householders to connect their drains satisfactorily with the sewers. In these instances the smell is not from the ventilators nor from the sewers, but from the houses themselves or the areas. From neglect of another

kind the houses in Brighton, as in London, are made often abominably odorous by the nuisance of dust-bins into which decomposing animal and vegetable refuse is thrown. There is no proof that the odours evoked from the dust-bin produce any form of specific disease, but they give the place where they are detected a bad name, and in time of anxiety a far worse name than it may deserve.

Altogether I found the working of the sewerage and drainage of Brighton entirely different from what I had been led to expect. I found no sewage deposit in the sewers; no leakage in the intercepting sewer; no special indications of escape of sewer air into houses; and as little of emanation from the ventilators as in London. I found, in short, nothing whatever that would lead me to believe in the occurrence of any special disease or mortality from bad drainage.

Connected with the sewers in the streets I found at convenient distances a series of manholes, leading down to the sewer, by which the men can descend by iron holds or steps. The sewers can be closed by a large wooden plug at the bottom of each shaft, and the shaft itself can then be charged with from two to three tons of water for flushing. These manholes or shafts in some cases are used as ventilators, the opening to them being covered with an iron grating; in other cases the grating is closed in with a covering of cement and stone. The covering is removable by the use of a key and lever. In addition, for the purpose of the ventilation of the sewers there are inserted in the lines of the sewers a series of open ventilators.

The rain and storm water is let into the sewers by trapped drains in the streets and by trapped drains from the houses. In many of the houses the water of the house that does not pass through the waterclosets, the water from the roofs and from the baths, is made to flow into an open air space in a back yard before it flows into the drain.

The soil-pipe connected with the houses is usually placed at the outside of the house, and in all new houses is systematically so placed. It is usually an iron pipe. In a large number of houses I found a ventilating tube, open at the top, carried from the top of the soil-pipe to a point above the parapet of the house. The pipe varies in size in different houses, from three inches in diameter to less than an inch—a ridiculous smallness. In the large majority of houses I found the watercloset system adopted, but there were some in which the old closet system, without water, is continued. The old pan watercloset is still in general use, but in many houses the better and safer closets by Underhay, Jennings, Bostel, and others are introduced.

It is correct for me to report that in the schools and in nearly all the institutions where numbers of the young are congregated, I discovered the utmost anxiety to have everything done that could effectively be done for the perfection of the drainage of the house, separation from the sewers and removal of offensive odours. In these efforts there has been great success, and I was unable to detect in any house I visited the bad smell which indicates a communication with the sewers.

#### THE ROADWAYS AND PAVING OF BRIGHTON.

The roadways and side paving of Brighton are on the whole exceedingly good. In some of the streets where the ascents are very steep and where the surface of chalk has not been overlaid by firmer material, there are considerable inequality and roughness with indifferent sideways, and in these situations there is, I am informed, the utmost difficulty in maintaining an equal roadway and sidewalk. During storms the water comes down in a deluge, and, when the street is narrow, sweeps all before it, rendering the firmest paving and road loose and insecure after a short time, although every possible provision be made for conveying away the water by the gully holes into the sewers. This carrying down of detritus from the steep streets into the main lines of thoroughfare is, I should assume, a cause of unusual trouble to the authorities, for I found, on going into some of the thoroughfares in the early morning after a wet night, a large accumulation of road sand and detritus into them, which must call for a great outlay of labour to secure removal. It must be removed, and the authorities, however active they may be in meeting this serious difficulty, are not always able to cope with it when there is a prolonged fall of rain. The main thoroughfares are kept in good repair, and the sidewalks are, as a general fact, sound and dry.

Recently along the Marine Parade an asphalt walking path is being laid down, which will prove extremely convenient to foot passengers.

#### THE SLAUGHTER-HOUSES, COWSHEDS, AND BAKERIES OF BRIGHTON.

In the course of my inspection I visited, in company with Dr. Taaffe and his chief inspector, Mr. Hawes, the slaughter-houses in Brighton, and in nearly every instance was present at the time when the men in the houses were at their work. The number I inspected, in actual occupation and work, was sixty-two.

The requirements of a perfect slaughter-house are—1. A good and efficient entrance and exit. 2. Good lairs in which the animals about to be slaughtered may be comfortably and cleanly housed, away from the slaughter-house itself, yet convenient to it. 3. A good clean slaughter-house, well drained, well floored, well lighted, well supplied with water, well furnished with all kinds of necessary implements and machinery, well provided with a place for slaughtering, with a distinct place for dressing the carcasses, and with good arrangements for removing the offal. 4. A wholesome place apart from the slaughter-house for storing the carcasses after they are dressed. 5. An outer place for collecting the refuse in such manner that it can be cleared off the premises as soon as the work of each day is done. 6. A staff of slaughterers and dressers who are rapid, humane, and efficient in the execution of their task, and who study to keep themselves and the place in which they work tidy and scrupulously clean. 7. Lavatories for the men, where they can rinse and wash their hands in basins set apart, and not in the pails in which the water for washing the carcasses is held, and, where they can dry their hands on towels specially supplied for that purpose.

I regret to say I cannot report any general adoption of these rules for Brighton. There is no public abattoir, and the private registered slaughter-houses are no better, as a rule, than those of London. With very few exceptions they are extemporised or imperfectly constructed buildings, arranged on no system whatever, and only kept commonly decent by the incessant watchfulness of the inspectors. It is just to report that I found one or two remarkable exceptions to this statement. In these exceptional houses, and in one of them especially, there were such excellent arrangements that were all like it nothing would be left to be desired. Unfortunately, these good specimens of slaughter-houses, in which the arrangements I have outlined above were systematically carried out, were but contrasts to very bad ones. In many instances the lairs were dark, dirty, and inconvenient; in other instances, though the lairs were better, the slaughter-houses were very bad. Generally where the lairs were dirty and close, the men at work were slovenly and dirty. In too many instances the lairage, the slaughter-house, the slaughtering were all equally at fault. There were, however, throughout, two saving clauses. The houses and lairs were connected with an open yard, so that ventilation was more efficient than could be expected at first sight, and the water-supply was abundant and good. Recently, good drainage has been enforced, and whitewashing of the walls of the inside of the building, by which offensive odours from the slaughter depôts are much prevented.

It was my intention to have reported on the slaughter-houses in greater detail, and to have named certain of them for which there is but one remedy—namely, to sweep them quite away. But inasmuch as I shall have to offer a recommendation before I conclude, which will have reference to a new and completely revised system, it is sufficient for me in this place to observe on the general conditions that were presented to my notice.

I inspected, with Dr. Taaffe and Mr. Hawes, the cowsheds of the town, to the number of forty, all of which are registered and under regular sanitary inspection. In these I found the greatest diversity. In some every attention was paid to cleanliness, to the admission of light, to the supply of room to the animals, to the purification of the stalls, to the drainage, and to the cleansing of the utensils. In others the commonest rules for the maintenance of cleanliness and of health were only maintained by incessant inspection from the officers appointed by the authorities, the directions issued from the department of the medical officer of health, and the attention of the veterinary surgeon to the health of the animals. The common faults were deficient space, closeness of air, inattention to cleanliness, partial cleansing of walls, in some cases, a perfect roofing of cobwebs on the ceiling, bad arrangements for storage of forage and food, imperfect arrangements for cleansing of utensils, and sometimes sad want of cleanliness in the attendants.

These faults in Brighton, as in almost all other large towns, were conspicuous. It is a bad and unwholesome practice enough to keep cows shut up in one place for months together, merely to yield milk for the population. It is very bad for the population, for the cows themselves, and for the profits of the owners of them, when the animals so imprisoned are deprived of the first essentials to health, pure air, clean bedding, clean food, and sufficient space in which to move and rest. I shall venture to recommend an improvement in relation to the cowsheds at the conclusion of this report.

I made an inspection of the bakeries of the town, and in one instance was exceedingly gratified with the practical and excellent arrangements which everywhere prevailed. The bakery in this instance was very large. In the smaller bakeries there was less convenience and order, but, compared with what may be seen in London and in many other large towns, Brighton stands out uncommonly well in the bakery department. I met with no cellar bakeries; I met with none that could be called uncleanly; in some of the smallest there was a strict attention to cleanliness, and, in brief, I did not see one from which I should have objected to eat of the bread prepared in it.

In summing up this part of the report, I should say that the slaughter-houses are as a whole no better and no worse than in other large towns where private slaughter-houses remain; that the cowsheds, generally, are neither better nor worse than in other towns; and that the bakeries are, comparatively, good.

#### THE COMMON LODGING-HOUSES OF BRIGHTON.

The common lodging-houses of all our large and populous towns are very liable to become centres of contagious diseases. These houses are, by the nature of their service, daily open to infection, since they receive new occupants every night, who come from different parts of the kingdom, wayfarers, the poorest of the poor. The houses are, as a rule, situated in poor localities, and are limited as to space. Brighton is no exception to these disadvantages, but, indeed, is rather a special sufferer from them. It has to supply eleven of these common lodging-houses, and they are placed in the north-eastern district, in Egmont-street, Derby-place, Chesterfield-street, and Cumberland-street. Accompanied by Dr. Tassie and Mr. Hawes, I visited every one of these houses and every room in them.

The houses are in an old and bad quarter of the town, many of them are in a dilapidated condition, and the rooms are low and small. The beds and beddings are poor, but in all cases clean. The staircases, the floors of the rooms, and the windows of the rooms, are kept very clean. The kitchens, where the lodgers cook their own food, are fitted with fair cooking appliances, are well supplied with water, and are clean and free from bad odours.

The yards at the back of these houses are open freely to the air and are fairly drained, but badly paved. In them are open closets, which are clean, but to which the water is not laid on. The closets are kept clean by the process of carrying water to them in pails. They empty into the sewer and the drains leading from them are trapped.

It will be seen from this statement, which I have endeavoured to make as precise and brief as possible, that these common lodging-houses are not of a kind to which the sanitarian would append any word of commendation. At the same time I must, in truth, admit that I discovered no disease present in them, except in one man, who had just returned from South America, and who was suffering from a remittent or intermittent attack, to which he had been subject, at intervals, for many months previously. He was lying in his clothes on one of the beds, but had been out in the day and had visited the out-patient department of the Sussex Hospital. The houses were fully occupied, and the beds, which I counted as over a hundred in number, were considered to be too few for the wandering applicants from all parts who were likely to require them. But there was no record of disease beyond what I have named, and I could not trace that the houses had been visited at any time by any class of epidemic affection.

I shall append a recommendation as to these common lodging-houses in the last part of my report.

#### MORTALITY OF BRIGHTON.

I have now to bring under consideration the important question of the mortality of Brighton, about which so much has recently been said and written. I have to inquire

whether there is anything that is exceptionally wrong in regard to the rate of mortality of this town; and, if there be, what are the causes of the error, and what steps should be taken to remove it.

In order to arrive at a clear understanding of this question I have availed myself of every reliable source of information. I have studied all the mortality returns for the past twenty-five years; the reports of the learned medical officer of health since the commencement of his labours, and the reports of the various medical and other charitable institutions. I have also had extracted from the local records of mortality the deaths of visitors occurring in Brighton during the past five years, in order to determine if visitors were subjected to any special risks from the contagious diseases or from other diseases that might be considered peculiar to the place.

Before I notice the details which I have been able to collect, it is necessary for me to treat briefly on the subject of mortalities in different localities and in the country at large. With my distinguished friends, Mr. Edwin Chadwick, C.B., and Dr. Wm. Farr, F.R.S., I have for many years past seized every fitting occasion for placing before the people the facts relating to these mortalities and the means of reducing the mortalities of our communities to what we consider a natural and model figure. At one time we were criticised as putting forward extreme views and as holding out hopes for the reduction of death-rates which were never likely to be fulfilled in our day. When we began to treat on this subject a mortality of 25 to 30 in the 1000 living was not considered remarkable, and when, therefore, we spoke of this as being more than twice above the natural average and twice what the natural average would be under proper sanitary regulations, it was no wonder that the assumed reduced estimate was considered as Utopian.

We have lived to see the day when the results have fully justified our expectations, which were, in fact, never too high; and we have lived, I am happy to say, to see the day when the public mind has not only become indoctrinated with our views, but so fastidious in relation to them that the death-rate of a town, in which residence is contemplated for a long or short time, is looked upon with as much care and attention as position in regard to railway accommodation, and the other conveniences and necessities which make life enjoyable.

At the present moment there are varying death-rates in English towns from the model low to the unnatural or excessively high. These may be divided in groups as follows:—

Group 1. Death-rate from 8 to 12 in the 1000			
" 2.	"	" 12 to 16	" "
" 3.	"	" 16 to 20	" "
" 4.	"	" 20 to 24	" "
" 5.	"	" 24 to 28	" "
" 6.	"	" 28 to 32	" "

There are very few towns as yet which have attained to the perfection shown in the first of these groups, perhaps none that through a series of years have attained to it. A few towns especially favoured in respect to population, situation, and wealth have attained to the position of the second group.

Brighton may be placed in the third group. The country altogether may be placed in the fourth.

It must not be considered that those towns which belong to the best of these groups are always favoured by having mortalities which lie within the figures stated above. In group 2 the mortality does not always come under 16 nor above 12. It sometimes runs over the one and under the other, owing to the effects of one or two interfering causes: (a) extreme reduction of temperature; (b) an outbreak of one or more of the diseases of the so-called zymotic type.

The first of these interfering causes occurs usually towards the close of winter, when great increase of cold succeeds upon a long interval of wintry weather. Then the feeble aged and the feeble young, together with those suffering from exhausting diseases like consumption of the lungs, die in great numbers and swell the mortality tables. The mortality from these causes is somewhat regular in its character. It is less in certain years than it is in others, because the seasons of some years are milder than of others; but it is always under certain rule, and can be calculated upon so as to be considered a fixed quantity, if a sufficient number of years to produce an average be taken into the calculation.

The second of these interfering causes is less certain in the order of its manifestation, and is most difficult to predicate upon, although the causes are, no doubt, under the direction of some simple, but as yet undefined, natural law. The general results over a large tract of country are calculable, and the general results in any particular time are also calculable when a sufficient number of years are given, through which to allow the seven to ten diseases that produce the mortality to take their course. But there is sufficient variability to cause at particular seasons the most deceptive appearances. Sometimes an unusual credit is given to a place owing to apparent freedom of mortality from the zymotic affections. At other times panic is excited in the same place because the zymotic diseases are so rife and fatal.

Two circumstances lead to these marked fluctuations in the mortalities from the zymotic affections. One is that the diseases themselves ordinarily attack every person once in life, but having once attacked, leave the person in whom they have been developed free from subsequent attacks. There are exceptions to this rule. Some persons escape the diseases, or certain of them, altogether. Other persons are susceptible to them all, or to certain of them more than once. But these exceptions do not materially affect our argument. In the large majority of instances, everyone born is liable to the diseases if exposed to the poisonous particles which lead to their development. There is, consequently, always growing up a population ready to become affected, which population, after it has passed through the ordeal of bearing the diseases, is acquitted of further evil from them. It happens then, sometimes even in large populations, that the diseases enter a susceptible community, scourge the members extensively, and then, the susceptible being either killed or protected by the attack, the place is left free from further pestilence until a new and susceptible generation has grown up in it, and a poisonous inoculation from without has affected those ready for its action.

In a previous page I have shown that Brighton has recently been subject to this serious invasion of disease after a long period of comparative immunity. I have shown that not one but three of the most fatal of the spreading diseases—viz., scarlet fever, measles, and whooping-cough—were present at one and the same time, and in the period of the year during which those diseases are most destructive to life.

It is necessary to keep all these facts in mind in estimating mortalities, because they account for the accidental variations. In the June quarter of the year 1881 the mortality of Brighton was 16.6, being as low on two weeks in the said quarter as 12.6. In the same quarter in 1882 it was 21.8, and in some weeks of the same quarter in 1882 almost double what it had been in the corresponding weeks of the previous year. Within those two periods the sanitary state of the town had not varied, but during and before the time a susceptible population was growing up ready for the invasion of the zymotic diseases which broke out in 1882.

The mortality of Brighton may be taken for the five years ending with 1881, as at the rate of 19.6 per 1000. In the first quarter of the present year it ran up to the rate of 29.2 owing to the epidemics so often referred to. In the second quarter of this year it fell back to 21.8 in the 1000, and in the present quarter it has continued to decline towards the usual rate of 19.6. If the death-rate in the present and coming quarter should correspond with the rate of the same two quarters of last year, the mortality of the five years ending 1882 will be 20.3 to the 1000, which may still be expected to be under the average of London, of twenty large towns, and of the kingdom at large during the same period.

From a theoretical point of view, resting possibly on the known laws of mortality in relation to population, these facts of the mean mortality of Brighton are what would be looked for. The relationships of population and mortality are so close, where a large mass of population exists in one town, that the fluctuations may, largely, be estimated by the population, and Brighton within the third range is in the place where it would be expected to be found when all the facts relating to it are considered.

It is urged, however, that Brighton from its position on the sea and from its being a health resort and place of pleasure ought to present a lower mortality than other towns of the same size that are less favourably placed. No one assumes that it could be expected to rival small seaside resorts of five to six thousand persons, where almost every

house stands in a garden, where there are comparatively no poor, where isolation from infection is perfectly easy, where there are no large hospitals, charitable institutions, nor workhouses, where the inhabitants are of steady number, and where the visitors come in much smaller numbers to enjoy themselves or seek for health.

But if Brighton cannot compete with such places in which the mortality is usually in the second range or even just within the first, it ought, it is said, to come within the second range as a general fact. Occasionally it comes near to the first range. It did so in the weeks ending May 7th and June 4th, 1881, when it showed a mortality of 12.6. Why is not this possible result more frequently repeated so as to give altogether a lower average?

The question is a reasonable one, and I am quite sure that nobody wants to shirk it, because to bring Brighton permanently into group two of mortality, in which it sometimes stands exceptionally, would be to make it all but a modern Hygieopolis in health as well as in beauty.

The causes which lie in the way to prevent this result are difficult to remove. They are mainly social in character. To understand them is the first step towards reducing them.

I. The first and most important reason why Brighton does not at all times present a mortality within the first and second groups are the density and rapid growth of the population. One hundred years ago the population of Brighton was about 3320. Fifty years later, in 1831, the population had risen to 40,634, and fifty years later still—namely, in 1881, it reached 107,953. From 1781 to 1831, the increase of population was at the rate of 66 per annum. From 1871 to 1881, it was at the rate of 1344 per annum. Meanwhile there has been no commensurate increase of habitation for the resident working population. An immense number of houses have been erected for the accommodation of visitors, but until recently the houses of the industrial people have remained much the same in regard to accommodation, but often doubly and trebly crowded, floors, in fact, being practically turned into dwellings, and sometimes one or two rooms fulfilling the purpose for which the whole house was originally designed. In this way multitudes have been massed together in confined space, and, moderately free from disease so long as there was no zymotic infection amongst them, have fallen rapidly under the infliction of such infection when ripe for it and subjected to it. It was amongst these classes that the large mortality of the present year was manifested.

II. Connected with the question of population is that of occupation. In the year 1794 the inhabitants of the town were carefully enumerated preparatory to a general inoculation of the place with small-pox. There were then 5669 persons in the town, and a large majority of these were engaged either as fishermen, low town or coast men, or as agriculturists, high or upper town people, who tilled the land. Now all these conditions have changed. In 1864 I found that the fishermen were only 240 in number, and that but one professed fisherwoman was extant. The agriculturists were also very few. At this day we may consider that 6 per cent. of the population is professional; 42 per cent. engaged in domestic work, taking care, for visitors largely, of houses, hotels, and institutions; 5 per cent. commercial; 3 per cent. agricultural; 35 per cent. industrial; and 9 per cent. indefinite and non-productive. The industrial, the domestic and indefinite classes are those who make the bulk of the population, 86 per cent. of it, and they especially are the persons exposed to danger from the spreading diseases. The industrial classes are the closely confined, the badly housed, and often badly fed and clothed. The domestic classes, in order to accommodate the visitors who support them, are closely packed, and suffer great trials from their dependence on good seasons for their maintenance. To these must be added a population of visitors, who would average 10 per cent. more, and who are present for health or pleasure, or both.

III. From these commanding causes of a higher rate of mortality than are likely to occur in less crowded towns, Brighton has another disadvantage. She is a town of schools. The delicate children of well-to-do and wealthy families are sent to Brighton because they are delicate. The children of numbers of families who are not well-to-do are sent to Brighton for the same reason, under the idea, by no means incorrect, that the proceeding is to the advantage of the health of the children, and is at the same time an economy in the long run. Hence every arrangement exists in Brighton for the education of children according to

the power of the parents to meet expenses. The end, as a rule, justifies the means, and anyone who, like myself, has visited the schools and learned how many hundreds of feeble children gain good health there as well as education would rejoice to recognise the benefits realised from such a centre of educational work. But the strain on Brighton is not to be forgotten. The fact that it is made the nursery of many delicate and feeble children, because they are so, is always to be considered in relation to the normal mortality. No town can possibly attain the first place for a low mortality so long as it is subjected to this risk; and the wonder is that the school mortality of Brighton is so inconsiderable as it is in the private schools. The fact speaks volumes for the air of the place and for the skill and thoughtfulness of the heads of its educational establishments.

IV. To crowded population, to large industrial and domestic in-door population, and to school population of the kind named, must be added as a disadvantage to the health of Brighton the constant influx of persons from the metropolis and other parts of the country who are suffering from disease, or are, if not themselves suffering from disease, in some dangerous way associated with it. Other towns are, no doubt, liable to the same infliction, but none like Brighton. Brighton can accommodate forty thousand visitors, and it is known to be a place where accommodation is certain whatever may be the emergency. Brighton is so familiar to everybody, it is one of the first places thought of when change of air is considered, and the change to it is so frequently attended with benefit that its reputation is universal; indeed, it labours here again under another risk—namely, that cases of illness are very often sent there, without discrimination, at seasons when they would be better elsewhere. But the great danger to Brighton under this head is its closeness to London, and its approach to London in the matter of conveniences and habits of life. A Londoner soon becomes accustomed to certain modes of metropolitan life which are essentially of London and of no other place. To him Brighton is a suburb of London. I remarked in my report in 1864 "that the business of the town is conducted so like that of London it is only necessary for the Londoner to forget the town he is in when at Brighton to feel that he is still in London. So Brighton becomes, in fact, the sanatorium of London. In illness people who can be removed fly to it for change of air; after bereavements families go to Brighton for change of scene, not unfrequently carrying with them particles of infection; during convalescence from acute diseases, especially from infectious diseases, the convalescents go down for a few days to complete their recovery."

V. It has occurred to several minds that as large numbers of persons come to Brighton in various stages of disease, and die there, the mortality of the town is increased from that cause alone. In order to arrive at the truth on this point I had the deaths of visitors in the town extracted from the general deaths for the five years 1877-81, together with the causes of death. The results may be epitomised as follows:—

In the five years 1877-81 the rate of mortality for the whole population, residents and visitors included, estimated on the mean of the population for that period, was 19·6 in the thousand.

In the said five years the rate of mortality in the resident population was 17·9 in the thousand.

In the said five years the rate of mortality of the non-resident population was 1·7 in the thousand.

On comparing the rate of mortality of the *resident* population in Brighton during the said period with other returns, I find that the 17·9 of that population stands to 20·1 for the united kingdom, 22·0 for London, and 24·2 for the nineteen large towns with which Brighton is classified in the Registrar-General's returns.

These facts being ascertained, it was necessary in the next place to determine the causes of the mortality of the *non-resident* population itself. Were these causes most dependent on infection or other influences connected with impurity of the air and local defects, or were they most dependent on constitutional causes under which those who succumbed were suffering before they came to Brighton?

To this question the answer is very definite.

The number of deaths amongst the non-resident population in the five years 1877-1881 was on the average 172·4 per year, of which 14·8 occurred from eight infectious diseases—namely, scarlet fever, 0·8; measles, 1·4; septicaemia, 0·6; erysipelas, 0·4; diarrhoea, 6·6; typhoid, 2; diphtheria, 0·4; whooping-cough, 2·6. There was no fatal

case among the non-residents from typhus, quinsy, croup, puerperal fever, carbuncle, influenza, dysentery, ague, glanders, or hydrophobia.

The deaths from the zymotic diseases which did occur amongst the non-resident population were mainly in the poor and crowded parts of the town, as the sub-district of St. Peter's. Out of 74 such deaths in the five years 7 only occurred in the Kemp Town sub-district; 9 only in the Palace sub-district; 5 only in the Preston sub-district. In 1877-78-79 and in 1881 there was not one death from zymotic affections in the Kemp Town division; in 1881 there was not one death from them in the Palace division; in 1877-79-80 and in 1881 there was not one death from them in the Preston division. In the St. Peter's division the average was over 10 each year—viz., 53 in the five years. The mortality was, clearly, amongst the poorest visitors, amongst those who were obliged to find a temporary home in the low and densely populated parts of the town. In the favoured districts the mortality from infectious diseases amongst the visiting population was but 4 per annum.

It is necessary to mention another point which comes out of a close analysis of the so-called zymotic causes of death. We have seen that zymotic cases amongst visitors yielded, annually, a mortality of 14·8 a year from 1877 to 1881, and that they included eight kinds of zymotic disease—scarlet fever, septicaemia, erysipelas, diarrhoea, typhoid, diphtheria, whooping-cough, and measles. But when we come to the study of each of the seventy-four deaths in detail it turns out that certain of the zymotic diseases were complicated with other diseases. One of the cases of erysipelas was in a person who was suffering from disease of the heart. One of the cases of diarrhoea was in a person who was sinking from senile decay. A second case of diarrhoea was complicated with marasmus—long continued wasting; a third with colic and congestion of the brain; a fourth with chronic mesenteric disease. One of the cases called typhoid commenced with muscular rheumatism, followed by acute meningitis. These six cases were not strictly zymotic, and ought to be removed from the list, by which removal the mortality from infectious disorders would be reduced from 14·8 per annum to 13·6. Twenty-two of the deaths from diarrhoea were in children under ten months old, and were most probably instances of that common kind of diarrhoea which is induced exclusively from bad feeding, and not from contagion or infection, a reduction from the list perceptibly justifiable, and which brings down the mortality of non-residents from contagious disease to 9·2 per annum. Finally, we have to recall the certain fact that some of these fatal cases of zymotic affection amongst the non-residents were cases of persons taken into Brighton while actually suffering from, or just after suffering from, the acute disease; so that we may fairly conclude that the mortality of visitors in Brighton from infectious disease in the five years last past has been under one per thousand per annum, taking the visiting population as averaging from 9000 to 10,000.

It will be inferred from these facts that the mortality amongst the non-residents in Brighton was due mainly to causes of a general or constitutional kind, from which those who came were suffering before they came, and for which the town was in no sense responsible. The deaths thus attached to the town amounted to a fraction over 157 per annum, and by a study of their causes the inference quoted is fully sustained. The record of causes shows that the persons who died were fatally stricken when they paid their visit to the town, and many of them, without any doubt, came as a last resource to regain health. Of the diseases ending thus fatally, pulmonary consumption takes the first place; next to it is bronchitis; after that, diseases of the brain and nervous system; diseases of the heart; cancer; senile decay; disease of kidney; disease of liver; diabetes; deaths by accident; sudden deaths; and one or two by suicide.

VI. One more cause of mortality in Brighton, much less definite than the above, but still not unimportant, is included in the fact that a very large number of persons who have accumulated a moderate income retire to this favourite place late in life, become residents there, and die there. If I dared hazard anything that was speculative into a report such as this, I might state, without much risk of departure from the strict record, many very important general facts bearing upon this question. I shall venture, however, no further than convey what I feel is within the bounds of simple justice—namely, that, no town in the kingdom is so

subject to residence of persons of advanced and worn-out lives; and that it is fair to assume an increase of at least 1 per 1000 to the annual mortality from this social cause alone.

#### SUGGESTED IMPROVEMENTS IN SANITATION IN BRIGHTON.

I come now to the last section of my report, in which I shall have to suggest such improvements as would, in my opinion, tend rapidly to bring down the mortality of Brighton to within at least the second of the groups of mortality described in the early part of the section immediately preceding.

In writing what follows I lay aside all knowledge of the possibility or impossibility of carrying out what is suggested by virtue of present legal powers vested in the Corporation. I shall suggest what seems to me essential, leaving it with the Corporation to apply for such powers as may be needed for these and other purposes, under the direction of their legal advisers.

I also lay aside all knowledge of what may or may not, for the moment, appear to be acceptable, in order to state, simply and plainly, what I, according to my best judgment, should carry out if responsible for the practical effort of making Brighton, as far as it can be made, a model health town.

1. I should as speedily as it can be done carry out the recommendation which the medical officer of health, Dr. Taaffe, reported to the Corporation on April 26th, 1877, for the improvement of the eastern portion of the town, under the clauses of the Artisans' Dwellings Act, 1875. This one improvement would, in my opinion, reduce the mortality at least 2 in the 1000 annually.

2. I should instruct the medical officer to make a similar report in respect to all parts of the town in which he detects, from time to time, an unusually high death-rate, or in which he observes that the death-rate is usually above 20 in the 1000, with a zymotic death-rate above 2.5. In all such places I should steadily endeavour to carry out the same improvements. By extending these improvements such exceptional death-rates as have occurred in the present year would be impossible.

3. I should carry out the medical officer's suggestion to establish in the eastern and western parts of the town a mortuary, so that the dead in the smaller and crowded tenements of the living may be immediately removed. Connected with these mortuaries I should build a courtroom for the service of the coroner in his judicial investigations.

4. In four different parts of the town I should erect a series of workmen's workrooms, in which no family should be allowed to live, but in which any person engaged in in-door work, such as tailoring, shoemaking, and the like, should be able, under proper supervision, to hire a workroom for a small sum per week. By this means the dissemination of disease by clothes and other articles made in rooms where the sick, dying, and dead are lying would be prevented.

5. The present public baths, established some years ago on the recommendation of Mr. Councillor Wood, are performing a most important service, and, as I found on inspection, are admirably carried out, and are doing an excellent business. They are, however, altogether inadequate for the wants of the town. I should extend these fourfold at least. The temptation they offer for personal cleansing extends to cleanliness all round—in clothing, in cooking utensils, in the house, in the mind. I am quite certain that this one further improvement would reduce the annual mortality another 1 in the 1000 in Brighton.

6. In connexion with the baths I should build washhouses and public laundries. The present system of laundry work in Brighton is not so bad as it is in many towns, for, as described in a preceding page, there are two good semi-public laundries. At the Grand Hotel there is also a model laundry in which an inquirer, if he be as favoured as I was by the managers there, may see the perfection of rapid washing, drying, ironing, mangling, and folding of every variety of clothing. This would be the model of the public laundries; and if they were erected another source of danger always imminent—namely, the conveyance of the poisons of disease by infected clothing would be prevented. In each of these establishments a heat disinfecting chamber for the reception of dangerous clothing would readily find its place and would be of persistent usefulness.

7. I should second most earnestly the recommendation of Dr. Taaffe for the erection in the town, in such portions as he would know to be best, of small public lavatories and watercloset conveniences for passengers of both sexes on what is known as the chalet principle. These conveniences would be essentially healthful, and would more than pay for their own cost and maintenance.

8. The erection of model lodging-houses to replace the present common lodging-houses is another improvement I should strongly urge. I do not say that the erection of such houses would be attended with less introduction of disease of a contagious nature than has occurred in the present houses; for, bad as they are, I must be just to them and re-state that I failed to trace any disease in them or from them. But it is common sense that they, as they exist, are a source of danger, and that new houses constructed on sound modern principles would be much the best in every way, morally, socially, healthily. Moreover, such houses managed by the direct authority of the Corporation would be kept under permanent and instant inspectorship and supervision.

9. The slaughter-houses in the town to which I have referred in a previous page, call for immediate attention. These are too numerous and extend over too large an area to be under efficient daily control, and although, as I have shown, one or two of them are excellent, the greater part are anything but excellent. I should, without a moment's hesitation, remove them one and all, and carry out Dr. Taaffe's recommendation for the establishment of a public abattoir, with efficient and cleanly lairs, proper killing places, proper dressing-rooms, with lavatories, waterclosets and other necessary accommodation for the workmen, and with cold storage rooms for the storage of carcases and joints. The claims of humanity and morality, as well as of health, demand this improvement. But health demands it specially. Connected with the proposed public abattoir, which would at all times be open to the public eye, I should recommend the appointment of one or two meat inspectors, who, like the present Jewish inspectors, should see that no carcase went into the market for human food that was not free from disease. Visitors coming to Brighton would then be assured that they had there an advantage which has for so many centuries been of such important service to the Jewish people; an assurance which, alone, would be a great attraction.

10. The public markets in the town call for improvement. All of them, meat market, vegetable market, and fish market, have become too small for the requirements of the town. They should be made model places of their kind.

11. There should also be added what, I am sure, would be an immense attraction to visitors and a great encouragement to health and good taste, a special flower market, where the poor who cultivate window gardens, as well as the horticulturists, could have flower stalls.

12. I have already referred to the cowsheds in the town. They are too numerous and widespread to be under constant efficient supervision. At best it is a most unwholesome thing to coop up cows for the sole purpose of making them turn vegetable food into milk. When this is done in the midst of a human population, in improvised sheds, in wrecks of sheds, in partial darkness and unavoidable dirt, in close air, and without the provision for the instant and complete separation of the unhealthy from the healthy animals, the business becomes more than a mere nuisance. It is a source of perpetual danger to health. I should recommend the removal of all the cowsheds from the town itself, and until they can be replaced by model farm dairies, should reduce them largely in number, place them outside the town, and have them so convenient for inspection that they can be under constant surveillance. In all the milk stores I should also insist that the constant water-supply was laid on. That a reduction in mortality would follow these improvements in the town of Brighton is absolutely certain. The typhoid milk epidemic of last year is a sufficient intimation of itself on this matter. It is not in the least a sanguine view to estimate that another saving of 1 life in the 1000 annually would reward this important change in the present system, besides giving the assurance to the world at large that in Brighton, a town of schools, the young who go there would have in the purest form the most common and important food for the springtime of life.

13. I should recommend very earnestly the erection of a larger number of drinking fountains in various parts of the town. These might be made objects of artistic beauty as

well as means of health, and the outflow from them could be usefully applied for flushing purposes.

14. The great ashpit, to the working of which I paid considerable attention, is not, I think, conducive to the health and welfare of Brighton. It ought, in my opinion, to be done away with altogether, and replaced by an arrangement by which the refuse of the town would be regularly removed each day altogether from it. If it were impossible to contract with any contractor to carry out this work, then I should suggest that after daily sorting of refuse, in order to retain what was useful, the residue should each morning be put on a steam barge, carried out a few miles to sea, and buried in the sea.

I would further strongly insist on an earlier and more regular removal of the refuse of the town. I saw several times dust-carts loaded with offensive refuse parading the streets of the town when they were filled with passengers, and emptying dust from houses at the time when the butcher, baker, and other vendors of food were distributing their produce. This is most unwholesome and utterly unnecessary. The general complaint of bad smells in the town will never be removed until this reform is carried out.

Bearing on this same subject the authorities might well enforce on all householders that everyone should have a movable dust-bin, so placed that the dustman can take it up at once, empty its contents into the cart, and replace it cleanly ready for the day's use.

15. The next suggestion I have to make is, in some respects, the most important of any. In many of the private schools of Brighton great benefit has been found to attach to the possession of a separate house, into which each scholar who is seen to be ailing is conveyed, and retained until the nature of the illness is declared. By this means the spread of infection is prevented in a very efficient way. I should urge the public adoption of this plan, with special reference to those great possible centres of infection, the board and voluntary schools. A few small houses for the temporary reception and isolation of the poor children of these schools when they are falling into infectious disease, would be the wisest means for stopping those calamities which have lately caused so much public clamour, and which are so detrimental to the town, and so severe upon the suffering population. By this plan 1 in the 1000 less of mortality would each year easily be saved to Brighton.

16. I come finally to what some would think the all-important question, the drainage and removal of sewage from Brighton. It will be gathered from what I have stated two or three times already, that I do not consider the present sewerage system in Brighton responsible for the outbreaks of zymotic disease which, during the present and latter part of last year, caused the exceptional death-rates. I should, nevertheless, in order to prevent in future the suggestion of such cause, recommend certain modifications in the present system, giving to them at the same time a direction towards the separate system, and towards the ready utilisation of the sewage whenever a practical and profitable plan for so important a purpose has been discovered.

I place my suggestions under four heads:—

a. I should increase enormously the present surface ventilation. This, in my opinion, is much more efficient ventilation than shaft ventilation, and I should extend it as follows:—

I should instruct Mr. Lockwood, in at least twenty parts of the town, and in such portions as he should see best, to open a communication with the sewer between one manhole and another, each as wide as the manhole itself, and well walled in on each side. I should cover over the entire length of each opening with grating, movable at certain parts, so that the sewer men may be able to descend to the open surface of the sewer beneath. At each end of these larger openings I should have doors that would close up the space or chamber, and, when necessary, I should fill all that space with water for flushing. The town might thus be speedily and regularly flushed from a limited number of points, at which a special water service could be laid on for flushing freely and effectually by a weight of water which could be made many numbers of proportions greater than is now possible.

b. To prevent all risk of the high town ever receiving sewer air from the low town I should adapt the suggestion of Mr. Lloyd Roberts, of Denbigh, for disconnecting one district from another. I should effect this by the introduction of large traps between one district and another, just as we trap a house from a sewer, only on a proportionately larger scale. By means of the large chambers I have sug-

gested above this separation could most readily be carried out.

c. In order to prevent the arrest of the flow of sewage in the intercepting sewer during the rising of the tide, I should utilise still further the furnace at Roedean. I should make that furnace work a steam pumping engine, the pump of which should be connected by a pipe from the Brighton side of the sewer beyond the flap which is used for shutting off the back sewer air from Portobello. I should make the engine, so soon as ever the tide began to rise, empty the sewer from the Brighton side, and pump the sewage, during the whole rising of the tide and until the fall, into the sea, by a channel provided with a series of valves, which being closed, one by one, as the tide rises, would still at the highest tide leave an escape above the water surface. In this way the intercepting sewer between Brighton and Roedean need never be locked at all, while its ventilation would be most effectively continued when the engine was in play.

d. In addition to these works the authorities should, I think, more earnestly insist than they have yet done on the importance to every householder, that he should separate his house from the sewer by an open grating; that he should most distinctly connect his house with the sewer by a good trap; that the soil pipe of his house should be freely open above the house; and that the present effete pan-closet should be replaced by the valve or syphon system.

It would, I think, also be worth while to indicate to the public the importance of catching, storing, and filtering the rain water which falls on the houses, and is now permitted to flow into the sewers. By payment of a very small rate all this soft water might be collected, purified, and applied to laundry and other purposes with the greatest advantage and economy.

In concluding this Report, Mr. Mayor and Gentlemen, I have to express my deep obligations to your learned and excellent Medical Officer of Health, Dr. Taaffe; to Mr. Lockwood; to the Resident Surgeons of the Medical Institutions, Messrs. Scott, Richardson, and Goode; to the Chairman and Secretary of the School Board; and to Mr. Hawes, the Chief Inspector of Nuisances, for the ready and efficient aid they have rendered me in my inquiries.

You requested me to report "completely and independently" on your beautiful town. I have endeavoured to the best of my ability to respond to that request, and

Have the honour to be, Mr. Mayor and Gentlemen,

Your faithful Servant,

BENJAMIN WARD RICHARDSON, M.D., F.R.S.

### THE TYPHOID EPIDEMIC AT PARIS.

THE rapid extension of the epidemic of typhoid fever in Paris is exciting considerable consternation, and well may do so. The mortality has increased fivefold in the course of three weeks: from 57 in one week to 134 in the next, and 250 in the third. The number of admissions into hospital has exhibited a corresponding increase, being 213 in the first, 536 in the second, and 1001 in the third, while on Oct. 19th the various hospitals contained no less than 2136 cases. Since then a slight fall in the number of fresh cases has occurred, which, it is hoped, indicates the commencing decline in the epidemic. The epidemic is most severe in the northern quarters of Paris, the mortality at La Villette being five times as high as at Montrouge. Of the 250 deaths in the last week, 42 were between the ages of five and fifteen, and 167 were between fifteen and twenty-five. It is conjectured that the extension of the disease may be connected with the return to Paris of many families, especially students and others, who have, during a holiday spent in the country, lost some of their acclimatisation; but, on the other hand, it must be remembered that the present season of the year is that in which typhoid most frequently assumes an epidemic form. The circumstances of the outbreak, however, unquestionably deserve the most careful study, since its extent threatens to render it one of terrible proportions. It is remarkable as occurring in a season of much and persistent rain, in which the chance of the contamination of drinking-water is usually regarded as small. But the household sanitary arrangements at Paris are notoriously of the most defective description—at any rate, if judged by English standards,—and the authorities may well direct their attention to this subject. In other respects the public arrangements seem to be ill-calculated to cope with so formidable an epidemic, for we learn that but two hospitals possess an apparatus for disinfection.

# THE LANCET.

LONDON: SATURDAY, NOVEMBER 4, 1862.

WE publish this week the exhaustive Report on the Sanitary Condition of the Borough of Brighton prepared by Dr. B. W. RICHARDSON on the instruction of the Mayor and Corporation of that town. This course has suggested itself as the fairest, at once to the Corporation of Brighton and to ourselves. Dr. RICHARDSON'S Report will command attention not only in Brighton, but also in every town and health-resort in the kingdom. The author is well known to have made sanitation a special study, and we cordially commend many of his suggestions for the improvement of Brighton and other towns. We may, without vanity, take the credit of initiating his inquiry, as well as that of Sir JOSEPH BAZALGETTE. Through them much good has already been accomplished, and more must follow. By our criticisms and comments Brighton has more than once been beneficially influenced, at the same time that nearly every other health-resort in England and on the Continent has been induced to look at home and "put its house in order." We claim the right to discuss the conditions affecting the public health of any town, well knowing that by this means reforms are inaugurated, defects remedied, and abuses checked. One instance may be cited as regards Brighton.

In the year 1862 Dr. WAKLEY, the Editor of this journal, while on a visit to Brighton noticed a black mass drifting in the sea opposite the town, and on which flocks of birds were feeding. Having ascertained that this was sewage matter discharged into the sea in front of the town by three separate outfalls, Dr. WAKLEY forthwith appointed a Sanitary Commission to investigate the matter and report thereon. Their memorable report appeared in THE LANCET on Oct. 11th and 18th, 1862. It set forth the principal causes of the evil state of things, and gave diagrams of the microscopical organisms and other sewage particles collected from the seawater immediately in front of the town. The sensation created by the publication of this report amounted almost to a panic, and at length led to an extension of the sewerage system, and the carrying of the sewage further into the sea by means of an iron pipe to a distance of one-third of a mile from the shore. This new system came into operation in the year 1864, and, bad as it was, robbed the sea of its grosser impurities, and effected some improvement in the sanitary condition of the town. With the increase of the population the evil of the plan became more and more obvious. In 1868 THE LANCET instituted another Sanitary Commission, whose report on the Drainage of Brighton appeared on Sept. 19th, 1868. Ten thousand cesspools were at that time still in operation, and though only four thousand houses were in communication with the sewers, the sea was polluted in the neighbourhood of the outlets and for a considerable distance around them. After a somewhat violent manifestation of temper the Corporation of Brighton set themselves seriously to work, and at length adopted the present sewerage system at an estimated cost of £150,000. When the new drains

were completed there was much we were able to approve, though we were compelled to point out that the sewage was carried eastward and emptied into the sea, instead of being taken westward to some distance beyond Cliftonville, and applied, partly by gravitation and partly by pumping, to the soil. We also pointed out the nuisance and danger of the open ventilators. The position we took then we still maintain. We wish, however, to repeat that our attitude towards Brighton and its corporation has always been friendly. We have had no interest to serve except that of the public health. As with other towns, we have exposed some of the defects of the drainage of Brighton and have endeavoured to enforce remedies. This constitutes one of the special functions of THE LANCET, and this function we shall continue fully, freely, and fearlessly to discharge. The Corporation of Brighton have been unnecessarily and unwisely irritated at some of our strictures and have committed indiscretions in holding public indignation meetings. More recently, however, — we record it with pleasure — wiser counsels seem to have prevailed, and many of the members of the Corporation have shown a genuine desire to ameliorate the sanitary condition of the town committed to their charge. There are good reasons for believing that, when they are unfettered by their disagreement with the Hove Commissioners, they will undertake radical alterations in their system of drainage and effectually improve it. For this consummation none are more devoutly wishful than ourselves.

DR. RICHARDSON'S observations on the sewerage and drainage of Brighton, and his suggested modification of the existing arrangements, are valuable. They are also remarkable for their coincidence with the views of Mr. BAILEY-DENTON, the well-known sanitary engineer, whose opinion we sought early in the present controversy, and whose Report was published in THE LANCET on the 5th of August last. It is due to this gentleman as well as to ourselves to repeat the following words which appeared in the Report referred to:—"I do not understand that it is either the duty or the intention of THE LANCET to point out how existing evils may be removed; how, in fact, a constant flow and discharge of the sewage may be effected, and the detention of foul matters to give off sewer gases avoided; how the separation of surface waters from the sewage may be secured; or how the sewers may be economically ventilated and the escape of deleterious gases and bad smells prevented." Mr. BAILEY-DENTON did, however, venture to point out that the authorities of Brighton and Hove might secure a constant discharge by the application of steam power to lift the outflow when it was impounded by the rise of the tide, observing that that desideratum could be effected by supplementing the furnace arrangements at Roedean with the necessary engine power. Dr. RICHARDSON proposes precisely the same thing when he suggests "the further utilisation of the furnace at Roedean by making it work a pumping engine for raising the sewage on the Brighton side during the period of the rising of the tide." At Brighton, where the intercepting sewer forms at each tide an enormous cesspool at the foot of the principal residential portions of Brighton and Hove, it really becomes a *sine qua non*, if the present evils are to be removed, that the constant outflow of sewage in-

dependent of tidal influences should be secured. There is no other town in England resorted to for health and pleasure where the same length of tide-locked sewer, subject to the sudden influx of storm waters, occupies a position so prejudicial to sanitary economy.

Upon the advantage of separating surface waters from sewage Dr. RICHARDSON and Mr. BAILEY-DENTON also agree. The doctor states: "I have been a consistent advocate of the separate system of drainage and sewerage all through my career,"—that the sewage from the houses should have "a perfect flow at all times, to ensure its delivery to whatever may be its ultimate destination," and "that the rain or storm water should be separately disposed of," adding that "in Brighton this system is not carried out." This negative statement of Dr. RICHARDSON'S is expressed by Mr. BAILEY-DENTON in these words: "The whole of the rainfall from the surface is admitted into the sewers and mixes with the sewage," the effect of which, he adds, is that when any large quantity of sewage has accumulated in the outfall sewer, when tide-locked, a sudden influx of rainfall necessarily expels the air still remaining in it and drives it by untrapped branch sewers or through faulty traps into dwellings.

Upon the question of leakage, Mr. BAILEY-DENTON gives figures showing that the quantity of diluted sewage collected during dry weather in the intercepting sewer each tide alone—i.e., in twelve hours—amounts to more than the whole daily water-supply—i.e., of twenty-four hours—of Brighton and Hove, an estimate which if only approximately correct, distinctly proves the influx of subsoil water. Yet Dr. RICHARDSON says the intercepting sewer is "well built, and cannot," *he thinks*, "permit leakage." As this point is much more important than appears at first sight—inasmuch as the collection of subsoil water in the sewer lessens the space for surface water—we recommend that the Brighton Town Council should refer the question to some independent engineer.

Dr. RICHARDSON presses upon the Council an increase of surface ventilation and the disconnection, by traps, of the sewers of the higher portions of the town from the lower, in the same way as all dwellings should be disconnected from common sewers. As regards the first of these objects sanitarians appear to be agreed that ventilation ought to be increased rather than diminished wherever it can be done without positive nuisance, and so long as the present system of things exist at Brighton increased ventilation in some shape or other must be adopted. No mode of ventilating or trapping of sewers, however, will be safe so long as the mouth of the outfall sewer is closed for thirteen hours out of every twenty-four, and the outfall sewer itself is subject to sudden influxes of storm waters; or so long as the houses in the town, to use a technical phrase, are not thoroughly "disconnected from the public sewers."

THIS is, in a special sense, the epoch of restraints, denials, and abstinences in the discipline of self and the policy of domestic life. Such progress as we are making is marked by a more or less philosophic abandonment of pursuits, pleasures, and habits, and the disuse of certain drinks, foods, and creature comforts which are, or are supposed to be, needless or harmful. It is impossible not to feel proud of the self-denying spirit that pervades society and the com-

munity at large, especially in the British isles, albeit, as KANT has most conclusively demonstrated, no genuine self-denial is practicable because the dominant desire or impulse at the moment of seeming to deny self is one of self-sacrifice. In a moral and mental way it is obviously possible to debilitate, instead of strengthening, the will by too much "swearing off" and protesting. It is expedient that a suggestion of this danger should be allowed to mingle with the counsels in favour of abstinences, which are just now so fashionable, and of which many "authorities" are perhaps a little too lavish. Abstinence from the use of tobacco is one of the forms of abstaining which are being pressed on the public with the energy of an active and full-blown fanaticism. We do not share the strong prejudice which finds its expression in this new counterblast. We have condemned, and shall continue to denounce, the abuse of tobacco, by its excessive, untimely, or inappropriate use. Many smokers smoke too much and take in too much of the smoke they make, others abuse tobacco by using it at wrong times and seasons, while to a third class, comprising the young and persons with special susceptibilities, tobacco is injurious in any form or quantity, and at all times, because, owing to the stage of development or some idiosyncrasy of the organism, the nicotine—which it is impossible to prevent passing off with the smoke—is in all doses hurtful and even poisonous. We cannot, however, join in the outcry against tobacco in its moderate and appropriate use. Our reasons for maintaining this position in a controversy, which would seem to be recurrent, will be most readily made evident by a short review of the physiological effects of tobacco, as that commodity is known to the smoker.

It is needless to summarise the properties which have been and still are attributed to tobacco in the text books. These are perfectly well known to the profession and have been repeatedly popularised for the public. It is with the vegetable product burnt in pipes, in the form of cigars or cigarettes, we have to deal. Practically this may be described as the dried leaves of the plant, either finely shredded or rolled nearly intact, in the former case burning very rapidly, in the latter being reduced to ashes perhaps somewhat less speedily, but with little delay. When tobacco is burnt in a clean pipe perhaps half the total quantity of the smoke given off is taken into the smoker's mouth. If an unclean pipe be used the same quantity of smoke is taken, but in the act of passing from bowl to stem the smoke probably takes up some of the old oil which has accumulated in the pipe. In the case of a cigar the smoke derived from the burning extremity of the roll of leaves is drawn between the layers of the latter with the result that probably a cigar is equivalent to a clean pipe until it has been burnt to the extent of two-thirds of its length, when it must be considered in the light of an often-used or foul pipe, because the heat and friction of the smoke have caused even the proximal portion of the burning leaves to begin to give off their oil. A cigarette is to all appearance, and perhaps, in fact generally speaking, a particularly mild form of pipe; but it must be remembered that the tobacco in a cigarette being very finely shredded and only loosely pressed together, burns more rapidly than the tobacco in the bowl of a well-loaded pipe, and that it is placed much nearer the mouth than in any pipe, except it

be the very short one used by navvies. It is therefore likely to happen that the habitual and almost continuous smoker of cigarettes—the man who seldom has one out of his mouth except at meals, and even then can scarcely refrain from a whiff—may in the course of the day consume a very large quantity of tobacco without perhaps being conscious of excess. The form of the “smoke” has, therefore, evidently a bearing on the amount of tobacco consumed. The mode of taking in the smoke is also important. Some smokers simply take the smoke between their lips, and, scarcely allowing it to enter the mouth, blow it out again; while others hold the smoke in the mouth, even carrying it back to the fauces, and occasionally ejecting it through the nose. The smoker who draws the greatest amount of smoke and keeps it longest in contact with the lining membrane of the air-passages undoubtedly takes the largest dose of the oil.

There are three points to consider—first, the local effects of the oily vapour from the burning leaves; second, the immediately contingent effects of the tobacco; and, third, its remote, or secondary effects. Each of these would call for special study in an exhaustive investigation of the subject. We cannot, on the present occasion, do more than suggest the line of inquiry to be pursued. As regards the local effects, it is especially desirable to be observant. There can be no question that the influence exerted on the mucous membrane of the lips, mouth, tongue, palate, epiglottis, larynx, and fauces, by smoking is important. There is first dryness, then hyperæmia of the membrane itself, next comes excitation of the nervous filaments distributed throughout the region, with direct irritation of the centres, and reflex stimulation of the glands. In consequence of this last mentioned set of effects, we get either increased secretion or very prompt emptying of the salivary glands, and either waste of the saliva, or the passage of that fluid into the stomach—probably at the time empty. The saliva is, moreover, to some extent impregnated with the oil derived from the smoke of the tobacco. It is easy to see how local disturbances, such as epithelial growths, innocuous or malignant indurations, and the like, may be induced by smoking; how the nervous centres connected with the various nerves distributed to the mouth, tongue, and fauces may be affected, how the salivary glands may be over-stimulated and exhausted, and how the stomach may be disordered. The passage of salivary fluid into an empty stomach may help to appease the appetite, but it can scarcely improve the digestion. Other local effects might be mentioned, but they will suggest themselves. Next come the immediately contingent effects of smoking. These may be either stimulating, sedative, or toxic, as the quantity of the nicotine actually introduced to the system—a very difficult point to settle—varies or the idiosyncrasy of the smoker may determine. The sum of the investigations that have been made in connexion with this phase of the subject would seem to show that nothing short of direct experiment in any particular case can supply the requisite data for determining how the smoking of tobacco is likely to affect an individual. And the deduction which may be hastily drawn from a few experiments will need to be qualified by the further consideration that the susceptibility of the organism for the influence of tobacco-smoking varies in a very special degree with those changes of state to which all systems, and specially those of the class of persons

who require or desire the use of tobacco, are subject. One man can smoke with the best results when he is hot, another when he is cold; one needs to have a full stomach, while another enjoys his smoke most in the early morning, or when he is hungry; one will take his pipe or cigar when he has to think, another must be idle to profit by it; and so on. With every change of mind, nerve-state, and condition of health, the susceptibility to tobacco varies. It is useless to try to lay down any precise law as regards its action. The use of the “weed” is in every case experimental, and its immediately contingent effects are incapable of prediction. As a rule, however, we believe they are, in the moderate use of tobacco, according to the individual taste, good instead of evil; but the patient, rather than the doctor, is the judge of results, and it is policy on the part of the latter to refrain from dogmatizing on the subject in any special case. The remote or secondary effects of tobacco-smoking are certainly not *cumulative*. There is not a particle of evidence which can be legitimately pressed into the service of the assumption—sometimes recklessly and unscientifically made—that they are so. A man may exhaust the strength of his nervous system and thus lower its tone, or he may impair his digestion, by habitual excess in smoking, but these results are in no sense cumulative, nor has the agent by which they have been produced been cumulative in its energy. The disastrous effects of tobacco-smoking—when too much is smoked or the tobacco is too strong—are those of persistency in the use of an injurious article, not a piling up of its effects. This is especially indicated by the state of the pulse in habitual smokers to excess. The sphygmograph shows a depressed state of the vessels while the smoking continues, and for a short time after a pipe, but the effect generally passes off when the use of the drug is abandoned for a few hours. So with the disturbance of digestion produced by excess in tobacco-smoking, and with its other “evil consequences,” which have been much exaggerated.

There is very little, if anything, to be said against the moderate use of tobacco in an average state of the organism. Those who are unfavourably affected by it should abstain, and it is wholly inadmissible in youth. We would go so far as to say that no young man should smoke before he has attained his majority, and it would be well if he deferred the use of tobacco altogether and in every form, until the extreme limit of development, which may be placed at the age of twenty-six. It is impossible to give any precept as to the time and mode of smoking. Personal sensibilities differ so widely that no common premiss can be laid down. Speaking generally, the points of caution should be to avoid—irritation of the mucous membrane of the mouth and fauces, loss of the salivary secretion, and super-excitement of the nerves and nerve-centres. Cigars are better than pipes, and far better than cigarettes; but no cigar should be smoked for more than three-fourths of its length, even with a mouth-piece. The smoke should be taken into the front of the mouth and ejected as rapidly as possible. Properly and moderately employed, tobacco-smoking is not a baneful habit, but one that may be reasonably enjoyed.

It is remarkable that two of the London Medical Societies have already discussed the value of operations for cancerous disease of the mouth. At the first meeting of the Clinical

Society Mr. GOLDING BIRD and Mr. CLEMENT LUCAS related cases of malignant disease of the tonsil and neighbouring parts, for which they had performed severe operations aiming at the entire removal of the diseased tissues. These cases afforded evidence of the boldness and skill of the operators, but will hardly encourage other surgeons to adopt a similar line of practice. At the Medical Society of London Mr. BRYANT and Mr. JONATHAN HUTCHINSON have spoken of the excellent results they have obtained in many cases of excision of the organ for cancerous disease, and expressed their conviction that the general estimate of the value of this procedure would have to undergo a considerable change, as the facts of more recent experience become fully known. It is very encouraging to hear two such trustworthy surgeons speak of patients being altogether free from recurrence of the disease for periods to be measured by years rather than months, and it is impossible to doubt that in such cases the operation has been eminently successful in prolonging life. In many of these cases the disease ultimately recurred, not in the mouth, but in the lymphatic glands, where it is not attended by the many distressing symptoms that render cancer of the tongue so particularly painful. And in this fact we can trace another distinct advantage from the operation. This fact, however, suggests important questions. Can it be that the disease which becomes obvious in lymphatic glands many months after the removal of the primary growth has actually started afresh in the glands? Or is it that some minute infected focus of the gland has remained quiescent for all that time, and then after a long interval has taken on its malignant activity? The prevailing belief is that these growths in the lymphatic glands are infective in their nature and truly secondary. And the mass of evidence in favour of this view is so great that it is almost impossible to reject it, although such cases as those alluded to by Mr. BRYANT require the supposition of a long period of latency in the infected glands. If this be so, the subject to which Mr. PEARCE GOULD has drawn attention, of the desirability of removing the lymphatic glands which receive their lymph directly from cancerous tissues, at the same time as the primary growth is excised, even although they show at the time no obvious signs of being affected, acquires great practical importance. It is impossible to avoid the question, Would these cases of Mr. BRYANT'S have been freed from cancer altogether if at the time of his operation he had removed the glands which ultimately became the obvious seats of the disease? Those who, like Mr. BRYANT, hold that cancer is at first a purely local affection, only defend operations when by them the entire local disease is removed.

At the Clinical Society Mr. HEATH and others spoke of the wisdom of removing cancerous glands. How much better might the results be expected to be if the glands were removed when they contain only the earliest germs of the disease, or possibly are quite healthy. It has been clearly established that a successful operation will often remove the primary affection, and the patient live for years without local recurrence, the operation failing only in preventing a secondary growth in the glands. But there is nothing in the nature of cancer of lymphatic glands by which it differs from primary cancer that should make surgeons look less hopefully upon early operations on one than on the other. Moreover, while glands can often be

removed before the disease has become advanced in them, they mostly lie quite superficial and readily accessible, and their excision is not an operation of great danger. In this direction, then, we may fairly look for further success in the operative treatment of cancer.

There is, however, another point of view from which these cases become of great interest. They are analogous to cases in which there is a true local recurrence of the cancerous affection long after an operation. In each alike some disease-germ is believed to be left behind, which after a period of latency suddenly or gradually—and often very rapidly—takes on active growth. This is the theory of the “localists,” unless they assert that a new fresh growth of cancer arises under the influence of the same local causes as induced the first. Is this period of latency due to some unfavourable constitutional condition, or is it a peculiarity of the local growth? We meet with cases illustrating all possible grades of rapidity of recurrence. After operations apparently equally complete and thorough, in some the disease reappears before the wound is healed, in others the recurrence is noticed after weeks only, in others after months, and in yet others after years. Is this variability due to local or constitutional causes? In other words, is cancer the purely local disease that it is often asserted to be? Without attempting to give a definite answer to this question, we must also ask whether there is any sure way of telling whether any given cancer will recur rapidly or tardily after its removal. The answer to this question depends upon the answer to the former one, and yet possibly this order will be inverted. For surgeons of large experience in these cases may be able to observe signs by which they can foresee a rapid or a delayed recurrence of a cancer, and by which, according to the character of those signs, they may be able to decide as to the purely local or partly constitutional nature of this malignant disease. An answer to this question would be of great service; for while many cases in which operation has been attended with success can be adduced, there are many others in which the result has been disappointing and grievous in the extreme; in which not only has the operation failed to do good, but in which it has, if possible, aggravated the patient's condition; in other cases, again, life has been subjected to serious peril with a minimum of benefit. Happily, in a large proportion of cases of cancer—when it attacks the breast, scrotum, lip or anterior part of the tongue—its removal is not attended with grave danger, and the risk to the patient's life is not such as to weigh for much either for or against operation. But in other situations—the rectum and the pharynx—the success of an operation for the removal of the disease is largely dependent upon the skill of the operator, and is necessarily attended with considerable danger to life. The question of how far it is justifiable to expose a patient to this risk when the most that can be hoped for is but a brief respite, is one that deserves the most careful consideration of surgeons, and a knowledge of any peculiarities in either the individual or the cancerous growth, which may be taken as signs of very slow recurrence, would here be of great value.

THE tendency to magnify the value of peculiar cases in medical teaching is one which, when carried to excess, is damaging to the interests of the ordinary student; and

nowadays, chiefly from a fear of appearing trivial by offering the simpler details of medical work, teachers and authors alike show a pleasure in dealing with the cope-stones of medical or surgical knowledge before they are assured that the foundations are securely laid. Whether we consult the regular text-books, special monographs, or the lectures of clinical teachers, a disproportionate amount of space will be found devoted to a record of cases valuable as much for their rarity, or perhaps as evidence of the brilliant results of treatment, as on account of their instructive worth to the reader. To the student or young practitioner these are but sorry guides in the labyrinth he is bound to tread; but, in reality, the evil is much in the nature of things, as the literature which deals with the ordinary diseases of ordinary people is apt to be voted trivial and dull, each one believing himself to be acquainted with such equally with his would-be instructor. And yet it is not unlikely that treatment is frequently based on an instinctive or rough application of general laws, with but little thought or modification for particular cases. It may be safe to tell the exact and well-informed practitioner to treat on general principles, and possibly the work in which little detailed attention is given to treatment may be useful to such; but for the average man more than this is required, and, left to himself, it is just possible that his patients may suffer while he gropes about attempting to find a safe course. In general practice, so much is needed in the way of attention to detail, such a constant necessity to adapt the treatment to the varying aspects of the disease, and we are so frequently consulted regarding points which, if too trivial to mention in print, are so difficult to deal with in practice, that a full exposition of these would often prove of inestimable advantage to the practitioner, especially to one of little experience. The same over-elaboration of unusual cases is noticeable in the teaching at our various hospitals and schools, as is evidenced by the large share of attention given to work in the wards as contrasted with that bestowed on out-door patients, even though the latter suffer from the diseases which in after-life the family physician will most commonly be called upon to treat. An obscure, rare, or sensational case is looked upon as a godsend to a ward, and students are called upon to devote a large portion of their time to the observation of diseases which they are not likely to find in their after-experience, and which, if found, they immediately hand over to the care of the special or hospital physician or surgeon. Were it possible that the whole of medical knowledge could be obtained or assimilated during the too brief period of study, such study would form a necessary part of hospital work, but under present circumstances this time is largely wasted in casual glimpses at imperfectly understood phenomena. The whole natural history of diseases, such as aortic aneurism or mephitic abscess, requiring perhaps surgical interference which they will feel unequal to, is known to many students who have no intelligent conception of the various forms of dropsy, who have perhaps had no opportunity afforded of following throughout a typical case of scarlet or typhoid fever, and who would feel extremely nervous if suddenly called upon to amputate a finger or satisfactorily introduce a Hodge's pessary. Of the chameleon-like phases of dyspepsia they know little, but are perfectly acquainted with the modern

operation of gastrotomy. Leaders and experts in the profession must necessarily devote both study and daring in pushing forward the limits of our knowledge, and without such men it is needless to say that our present proud position could not have been gained. Specially rare and interesting cases must continue to occupy a large portion of professional and more especially periodic literature, and in later periods of study all intelligent men will interest themselves in such; but the fuller consideration of the more common and happily less serious ailments, both in our text-books and our hospitals, would be an incalculable boon to the general practitioner suddenly required to meet all the emergencies of ordinary practice, and to depend solely on his own resources.

## Annotations.

"Ne quid nims."

### THE ARMY MEDICAL SERVICE IN EGYPT.

THE apathy and indifference with which the claims of the medical officers to a fair share of the rewards bestowed for service in the field have hitherto been too generally treated, and the grudging recognition which has been accorded them, has been the subject of comment after almost every war. But when a question of supposed neglect of duty, of inefficient arrangements, or inadequate preparation for the contingencies of a campaign is started, there is an immediate change of scene: apathy is replaced by fervid zeal, and there is no lack of persons eager to take part in the attack upon the doctors. Of this not very chivalrous course we have again had an instance in the Egyptian campaign. When a vote of thanks for the great services performed by the army and navy was moved in Parliament no one had a word to say regarding the omission of the medical officers, though the head of that branch was of sufficient rank to have entitled him, had he been one of the lucky combatants, to have been included among the officers named in the vote. But when the subject of an alleged breakdown was brought forward there was no want of honourable members to put questions which implied at least a belief in the charges against the department, many of which had already been proved to be groundless. The same thing occurred after the Zulu war, questions having been put which Colonel Stanley characterised as the "unfounded, he had almost said the foul, aspersion." Mr. Childers, on Monday last, repeated the information he had previously given that he had appointed a committee to inquire into the allegations which have been made as to the inefficiency of the service, and he defended the composition of the committee as a "strong one calculated to act fairly to all concerned." He has since then added to it the name of Sir R. Lloyd Lindsay. In reply to subsequent questions on the subject he stated that while he would not pledge himself to lay on the table the report of the committee and the evidence taken before it, he could not see any reason to the contrary, and as at present advised it would be done. The form in which the question was put by Mr. Carington, coupled with a remark of Mr. Childers "that strong pressure from different directions had been put upon himself," appears to bear out the opinion we recently expressed that these charges against the medical officers seemed to be brought mainly with a view to discredit the present organisation of the department. We are satisfied to take Mr. Childers' description of the committee, which we believe will make a thorough, honest, and searching investigation into the working of the medical service. That

individual instances of shortcoming may be found we can readily believe, but we have full confidence that the result will be to show that the medical officers as a body did their work fearlessly, skilfully, and zealously, and that any deficiencies in the medical arrangements of the late campaign were the result of circumstances which, so far as the department was concerned, could not have been foreseen and which it was quite out of its power to control.

### SEWER GAS AND ITS DANGERS.

THE injurious effects produced by the escape into dwelling-houses of emanations from sewers have been so thoroughly ascertained and are so generally admitted, that probably no one would venture directly to deny them. Nevertheless, we often see in practice arrangements accepted in the drainage both of separate houses and of districts which must necessarily lead to evil results, showing that the danger, if not formally denied, is often regarded as of little moment. It is still sometimes asserted that sewer gas in itself is incapable of doing any harm. It is therefore necessary from time to time to point out to the public the real nature of the danger which is thus incurred. In the first place, there are in the emanations from sewers the chemical products of the decomposition of animal matters, as sulphuretted hydrogen, ammonia, &c., to which the offensive smell is due. Now, these gases in themselves, though disagreeable and doubtless prejudicial to the health, are incapable unless highly concentrated, when they act as rapid poisons, of causing serious disease, and when diluted are chiefly important as indicating the fact of sewage emanation, and consequently the presence of the really injurious elements, which are themselves inodorous and imperceptible to our senses. These elements are probably the microzymes which germinate in sewage, especially when pent up and stagnating. These microzymes are of various kinds and properties. Firstly, the microzymes of putrefaction and the septic processes, which differ greatly in their virulence according to the conditions under which they are generated. To these may be ascribed the low sore-throat, the diarrhoea, and the many non-specific diseases which sewage emanations so often give rise to. The presence of these germs will also often convert any simple inflammation into a spreading or erysipelatous one. Next, in sewage gases the microzymes of various specific diseases, especially typhoid fever and diphtheria, are liable to occur. These, no doubt, are not always present, and we often see instances of pro-longed sewage contamination both of the air and drinking-water of houses without these affections showing themselves; then, perhaps, the poison gets introduced and an outbreak takes place. But there is probably no town of any magnitude in England, and certainly no health-resort frequented by convalescents, where these poisons are not certain, sooner or later, to be introduced; and, given the conditions necessary for their germination and dissemination, we shall find these diseases endemic with occasional epidemic outbreaks. The conditions which especially favour the development of these poisons are stagnation of sewage and want of free ventilation; indeed, many high authorities believe, as did the late Dr. Murchison, that under these conditions the poison of typhoid fever may be generated *de novo*; and recent researches on the microzymes of disease would give support to this view, as they show that these organisms are capable of being extraordinarily modified by the conditions under which they germinate, so that it is possible to conceive that microzymes generally harmless may, under favouring circumstances, develop into the germs of specific disease. Any system of drainage which causes the sewage to stagnate, or be pent up for however short a time, or under which the sewage gas is liable to be forced

back into the houses, must be regarded as essentially faulty, and tolerably sure, sooner or later, to give rise to the most injurious consequences.

### SUPRA-CLAVICULAR PSEUDO-LIPOMA.

A FEW months ago M. Verneuil described, in the *Gazette Hebdomadaire*, an affection to which he gave the above name. It is characterised by a swelling in the supra-clavicular region; which transforms the usual depression to a prominence, two or three centimetres above the level of the adjacent parts. It occupies the space left free between the clavicle, the sterno-mastoid, and the trapezius. The swelling is elastic, not tender, nor is there any change in the colour of the skin. The subject has been lately studied by M. Potain, who has read a paper on it in support of his candidature to a place in the Académie de Médecine. He has observed twenty instances of this condition during the last three years, and confirms Verneuil's description, pointing out, however, that a slight prominence in this situation is common in stout persons, and may be regarded as physiological. Four of the cases were men, and sixteen women; almost all, like those of Verneuil, were rheumatic subjects, and presented unmistakable manifestations of their diathesis in vague pains about the joints and muscles, and not infrequently evidence of slight arthritic changes, amounting in the majority to distinct painful swelling of many joints, especially the knees, wrists, fingers, and tibio-tarsal articulation. The urine in many cases presented deposits of uric acid. Three of the patients were diabetic, and all had a fair amount of subcutaneous fat. In some cases the swelling exceeded the limits mentioned above, and similar swellings are sometimes met with in other situations, at the sides of the patellar tendon and of the tendo Achillis, in the neighbourhood of the malleoli, less commonly below the occipital bone, in the temporal, parotid, and submaxillary regions—in short, in various situations in which the loose cellular tissue, which habitually contains a good deal of fat, is susceptible of the deposit of an excessive quantity of fat or of serosity. A similar condition is sometimes seen in slighter degree at the backs of the hands. Distinct oedema of the cellular tissue is often associated with these pseudo-lipomata without the coexistence of any of the usual causes of oedema. It was present in eight of the cases, and is often to be found, M. Potain believes, in cases of the rheumatic diathesis, whether the more definite rheumatic symptoms be acute, subacute, or chronic. He suggests that both the oedema and the overgrowth of fat are the result of the same morbid tendency.

### CANADIAN AND AMERICAN HOTELS.

IT is time the travelling public were warned of the dangers attending a lengthened stay in an American or a Canadian hotel. With few exceptions, these hotels have fixed wash-basins, with hot and cold water laid on, in the majority of the bedrooms, and very frequently a bath and other convenience in addition. In the private houses of wealthy Americans, who are favourable to luxurious living, this same system is almost universal. An examination of many of these basins and of the plumbing arrangements has brought to light the fact that they are frequently untrapped, and that when traps are used, they are of a bad pattern, and calculated to create danger to the health of the occupant of any room or house where they are placed. A few weeks ago, a correspondent of THE LANCET was placed in a bedroom where there was a fixed basin which communicated directly with the sewer without any intervening trap. He was made seriously ill by sleeping one night in this room with the windows wide open; and although he placed the plug in the basin and filled it with water, the whole of the water was sucked out through the waste-pipe during the night, and the

room filled with sewer gas. At the end of September another visitor was equally poisoned, and he found the waiters in the dining-room engaged in making a careful search for an escape of sewer gas, which was painfully apparent in that apartment. Remonstrance at the office of the hotel elicited the remark from the clerk in charge that he feared the sewage must have bubbled over again, but he was unaware that the basin was untrapped. Inquiry showed it was the common report that in some cases the sewage had forced its way into the basins in the bedrooms. It is not too much to say that it is dangerous for any adult to reside in an hotel with such imperfect sanitary arrangements, and that the air of the room would not improbably cause death to a delicate child. In very many hotels in America and Canada bottle or cesspool traps are used under the basins, in which the sewage ferments, and so sewer gas is liable to be generated in every room which has a fixed basin. We must warn travellers to be careful before retiring to bed or remaining for any length of time in an hotel where the arrangements are as we have described. It would be a public service for one of our contemporaries in America to fearlessly expose this great danger to the public health.

#### EGYPT AND THE MECCA PILGRIMAGE.

THE Egyptian campaign, by reducing the number of pilgrims to Mecca, would, we anticipated, have the advantage of lessening the probabilities of an epidemic. Indeed, this consideration more than compensated the slight risk of cholera involved by the importation of Indian troops into Egypt, which so much alarmed our French neighbours, that, under the direction of Dr. Fauvel, Inspector-General of the Sanitary Services of France, official remonstrance was addressed to the English Government. The early termination, however, of the campaign has enabled a far larger concourse of Egyptian pilgrims to gather round the sacred shrine; and though as yet no epidemic has broken out, we cannot but feel that while our troops are still in Egypt, the risk is to us a matter of great concern. The sanitary services must have been considerably disturbed by the war. Will they be satisfactorily re-organised before the return of the pilgrims? The pre-occupations arising from military and political matters must not be allowed to take precedence over these all-important health questions. Our neighbours, in any case, are fully alive to the danger. Cholera in Egypt, it is felt, would mean an epidemic spreading throughout the entire basin of the Mediterranean. From all sides we receive protests and warnings. Dr. Bradel, of Bulgaria, writes that he is alarmed because the 5000 or 6000 Turks living in Bulgaria still send pilgrims to Mecca, who return *via* Varna in a filthy condition, with boxes containing clothes which have become so foul during the journey that last year no one could be persuaded to open or to move them. Professor Felix, of Bucharest, has been urging the Austro-Hungarian Government to appoint a permanent scientific commission, while Dr. de Csatory, of Buda-Pest, is agitating in favour of an international convention between all nations who have equal laws relating to public health. As, however, we are not acquainted with any two nations that have equal laws on such a subject, it would obviously be most disastrous if countries like England, which have gone far in advance of other European nations in sanitary legislation, should be brought back to their low level. But when Dr. Csatory further proposes that the contracting nations should abolish all impediments to free intercommunication and commerce, he shows himself more in harmony with the feelings and interests of the age in which we live. To these somewhat elaborate schemes Dr. Raymondau, of Limoges, adds a more practical suggestion. He proposes to organise an ambulance service in a manner similar to that of the Red Cross Society, but

whose mission it would be to follow in the wake not of wars, but of epidemics. Finally, Dr. F. Ovillo, of the Spanish army, and late medical officer to the Sanitary Council of Morocco, has published a pamphlet insisting that in Morocco everything existed that could favour the development of disease, especially cholera. This state of affairs is a perpetual menace to Europe, and cholera in Egypt would become infinitely more dangerous by the prospect of its spreading to Morocco. He therefore maintains that the European powers should bring special pressure to bear against Morocco, and establish a sanitary bureau in that country, with power to act independently of the local native authorities. Further, it is urged that no ship should be allowed to convey the "Hadjis" from Mecca to Morocco without undergoing the strictest sanitary supervision. Altogether, therefore, if mischief results from this year's pilgrimage, it will not be for want of warning; but we trust we shall add to the triumphs already achieved in Egypt that of successfully protecting Europe against the danger now causing so much anxiety.

#### THE PARKES MUSEUM.

THE first general meeting of the Parkes Museum was held, in accordance with the Act of Incorporation, at the new premises in Margaret-street, W., on October 28th, at 3.15 P.M. Among those present we noticed T. Twining, Esq., George Godwin, F.R.S., Professor De Chaumont, Captain Douglas Galton, Dr. W. Wood, Professor John Marshall, Miss Davenport Hill, L.S.B., Professor Corfield, and many others interested in sanitary progress. The Secretary, Mr. Judge, having read the notice convening the meeting, it was proposed by Mr. Twining and seconded by Mr. Geo. Godwin that H.R.H. Prince Leopold, Duke of Albany, be elected President of the Museum. This having been carried *nem. con.*, the following were unanimously elected Vice-Presidents: The Duke of Northumberland, the Duke of Westminster, K.G., the Earl of Derby, K.G., Earl Fortescue, the Right Hon. Sir R. A. Cross, G.C.B., the Baroness Burdett-Coutts, Sir Joseph Fayer, K.C.S.I., Edwin Chadwick, Esq., C.B., Professor T. H. Huxley, Professor John Tyndall, R. Rawlinson, Esq., C.B., and Miss Florence Nightingale. The following were then elected to form the first Council of the institution: Captain Douglas Galton (Chairman), Dr. Poore (Vice-Chairman), Mr. Charles Parkes, Mr. A. Waterhouse, A.R.A., Mr. Twining, Mr. Rogers Field, C.E., Mr. E. C. Robins, F.R.I.B.A., Professor Hayter Lewis, Professor Corfield, Mr. Geo. Godwin, F.R.S., Professor John Marshall, F.R.S., Dr. Sieveking, Dr. Russell Reynolds, F.R.S., Dr. Steele (Guy's Hospital), Dr. Gowers, Mr. Berkeley Hill (Treasurer), and Dr. Dawson Williams (Hon. Secretary). A vote of thanks to the Chairman was next proposed by Professor De Chaumont, and Captain Galton, in responding, reminded his audience that the Parkes Museum had now entered upon a new phase of existence; it had reached an independent position, and for the first time had a building of its own, to which all who desired to use it either for purposes of teaching or learning would be welcome. They commenced their new life under the special protection of a distinguished member of the Royal Family, and with the co-operation of twelve Vice-Presidents, each of whom was well known for his philanthropic or scientific labours. They had every reason to believe that the Museum would meet a great public want, and that the assistance of the public and of the scientific professions would not be withheld from it. The Council would endeavour to make their new home as nearly perfect, hygienically, as possible. The drainage arrangements had been carefully planned by Professor Corfield and Mr. Rogers Field, and it was intended that they should be so constructed as to be available for teaching purposes. He was pleased to

announce that Mr. Rogers Field had made the handsome offer not only to supervise the construction of these arrangements, but also to bear the whole expense of them. The lighting, warming, and ventilating of the Museum were being carefully considered by a special committee, and every endeavour would be made to make each of these arrangements a model worthy of imitation. Their friend Mr. Twining, to whom the Museum was deeply indebted, had undertaken at his own cost the supervision and arrangement of the food collection. The whole collection would be carefully weeded and rearranged, and it was hoped that the active work of the Museum would begin again soon after Christmas. These remarks brought the proceedings to a close.

#### THE LATE MR. ARTHUR, M.B.

MR. JOHN FINDLAY ARTHUR, M.B., C.M., of Aberdeen University, whose melancholy death has aroused the sympathy of the whole country, was a son of the Rev. D. F. Arthur, minister of the Free Church at Banchory-Devenick, near Aberdeen, and graduated in 1873. Leaving St. Pancras, London, by the 9.15 P.M. train on Saturday, he occupied a berth in the rear-most part of a Pullman car, and all went well till after leaving Normanton. After leaving this station, and while the train was proceeding at a very rapid rate, the cry of fire was raised by the attendant, who, along with other three occupants, rushed madly about the carriage, and endeavoured to communicate with the driver. It does not appear that Mr. Arthur ever left his berth, and it is only certain that when the train was ultimately brought to a stand and the flames extinguished the unfortunate gentleman was found dead, and the body fearfully charred and almost unrecognisable. It is not decided whether the fire was occasioned by the overheating of the stove, or by a spark from the cigar of Mr. Arthur himself. His brother, who is in practice at Cultra, near Aberdeen, had received a telegram, asking him to meet Mr. Arthur at Aberdeen station on Sunday, and the shock to the family on receipt of the sad intelligence was very great indeed. Both as a student, and among those who knew him since, Mr. Arthur was much admired for his genial disposition, his high talents, and commanding appearance, being a man of fine physique. As a student he distinguished himself in several classes, and after graduating he proceeded to Ceylon, where he received a Government appointment as district medical officer at Dimbooka, and soon gained for himself an excellent position. About two years ago, while riding to attend a patient in a distant part of his district, he met with an accident which necessitated his coming home for professional advice, but after seeing some friends in Aberdeen, he returned to Ceylon for a short time, and five weeks ago left there again for home. Mr. Arthur, who was about thirty-three years of age, has two brothers who graduated at Aberdeen in 1880: one is in practice as above-mentioned, and the other, we believe, is medical officer at Ben Rhydding Hydro-pathic Establishment. We would assure the near relatives of Mr. Arthur of the deep sympathy of the profession.

#### THE PREVENTION OF INJURY TO HEALTH.

IN connexion with an effort to improve the navigation of the river at Lymington, an accumulation of mud deposited in its bed, and containing sewage matter, is being heaped up in one of the marshes in front of houses in the Bath-road, and in view of the opinion of the medical officer of health to the effect that danger to health might be anticipated from it, the Local Board of Health passed a resolution to serve a notice on the contractor carrying out the works, requiring the abatement of the nuisance and the removal of the mud within four days. No action was taken on this

notice, and within a few days the Local Board met again, and by a majority of three rescinded their resolution, determining to take no notice of the mud accumulation for the present, and this notwithstanding the protest of the medical officer of health, who again called attention to the danger incurred, and of another medical practitioner, who reminded the authority of the serious results which, as we recently pointed out in connexion with Dr. Airy's official reports on diphtheria, had followed a similar proceeding at King's Lynn. The grounds for this reversal of a previous decision were several, but one which was strongly pressed deserves notice. It was that persons had lived near the locality for a long period without being injuriously affected by the sewage mud. In using such an argument—and we regret to say that it is by no means unusual—sanitary authorities seem to forget that one of their principal duties is the prevention of injury to health, and that it is no part of their functions to await the production of the very condition which their preventive measures ought to render impossible.

#### ERYSIPELATOUS ORGANISMS.

IN several patients suffering from erysipelas Fehleison has found micrococci to be constantly present in the lymphatic vessels of the skin in the parts invaded by the inflammation. He has endeavoured to ascertain whether these organisms can be regarded as the veritable cause of the disease. The method of his proceeding (according to an abstract which has appeared in the *Gazette Médicale de Paris*) was to excise minute fragments of skin, having first washed the surface with ether and with a solution of corrosive sublimate. These fragments were afterwards placed in gelatine prepared after the method of Koch. The micrococci rapidly grew, forming an abundant vegetation around the small fragments. By means of a platinum needle the mould was transplanted from one spot to another on the surface of the gelatine, and a thin membrane formed around each point of inoculation. The colonies of micrococci grew slowly, and at the usual temperature of the air their development soon became arrested. The organisms appeared identical in appearance with those seen in the fresh preparations, except that in the gelatine the micro-organisms formed longer chains. Fehleison tested the virulence of the fourth generation of these organisms by an operation which most of our readers will probably agree with us in considering wholly unjustifiable. He inoculated the germs in the skin of the gluteal region of a woman, aged fifty-eight, suffering from multiple fibrosarcomata of the skin. The inoculation was made by five punctures with a lancet. Up to that time the temperature of the patient was normal. On the evening of the inoculation the temperature was 37.7° C., but the next day the woman had a slight rigor, headache came on in the course of the day, and in the evening the temperature was 38.8° (101° F.). On the morning of the third day it was 37.2°, and in the evening 37.8°. On the fourth day another rigor occurred, and there was found on the left buttock an erythematous patch, prominent and circumscribed, having all the characteristics of erysipelas, and during the day it spread considerably in extent. The temperature was 40.4° (104.7° F.) in the morning, and 40.6° in the evening. On the fifth and sixth days the temperature was 41° C. (105.8° F.), and on the latter the woman fell into a state of collapse, from which she was roused by a subcutaneous injection of ether. On the seventh day the erysipelas occupied an area of a square foot. It remained stationary during the next three days, the temperature oscillating between 39.2° (102.6° F.) and 40.6° (105° F.); then the erythematous patch began to subside, but the temperature continued raised, and even on the thirteenth day was 40.0° (104° F.), but after the fifteenth day it was normal. As a consequence the infiltrations of the skin

seemed to have slightly lessened. The author remarks that erysipelas can readily be communicated to rabbits, especially if the inoculation is made upon the ear. We echo the hope expressed by the editor of the *Gazette Médicale*, that those who endeavour to corroborate the observation, if rabbits do not suffice for their needs, will have the courage to operate on themselves.

#### NEW ZEALAND LUNATIC ASYLUM REPORTS FOR 1881.

THE post of inspector of asylums being vacant by the death of Dr. Skae, the reports have been furnished by the deputy inspectors and superintendents. These state that at the end of 1881 there were 769 males and 406 females in the seven asylums of the colony, being an increase of 40 men and 16 women on the previous year. The relations which these figures bear to the sexes in the whole population are not stated. The disproportion between the two sexes seems very large, even in a colonial population, while the rate of increase might be assumed to be not in excess of the increase of inhabitants. The statistical tables are founded on those of the Medico-Psychological Association, and give the satisfactory result of 44·01 of recoveries on the admissions, the deaths being only 5·55 on the number under care. The re-admissions—87 in a total of 359 admitted in the year—point to a wholesome freedom in the discharge of patients. The table of the nationality of the insane shows that of the 1175 insane persons only 71 were born in New Zealand, while 346 were natives of Ireland, and 402 of England. Here, again, a comparison with the statistics of the general population would be of interest. The ascribed causes of insanity correspond very closely to those found in English asylums. In the causes of death, 27 out of 63 are ascribed to general paralysis, a larger proportion than the home statistics yield. Only one suicide is reported, and one fatal casualty. The Colonial Legislature seems to be actively alive to the importance of preventing the importation of insane persons, having passed an Imbecile Passengers Act, to deal with such cases. Might not the Home Legislature, with advantage to the community, take a hint from this? From the general tenor of the various reports, the conclusion may be drawn that the medical officers are striving actively in the direction of employment and amusement for the insane, and improvement in the quality of their attendants, the views expressed invariably advocating increased liberty and comfort for the patients.

#### THE FERMENTATION OF NITRATES.

THE researches of Schloesing and Muntz have shown that the formation of nitrates in the soil and in organic liquids is due to the development of aerobic organisms. Certain facts recorded by Boussingault, Schloesing, and others have suggested to MM. Gayon and Dupetit that the opposite process, the reduction of nitrates, may also take place in a similar manner. The results of an investigation which they have made has been communicated by them to the Académie des Sciences of Paris. To street drain water nitrate of potash was added in the proportion of ·02 gramme per litre, and then some decomposed urine. The nitrate disappeared gradually, and the liquid became filled with microscopic organisms. Successive cultures of these enabled the experimenters to effect the reduction of one and even two decigrammes of nitrate of potash per litre. By employing decoction of chicken as the basis they were enabled to decompose as much nitrate as amounted to 5 per cent. of the liquid. That the organisms which developed under these circumstances were really the cause of the denitrification was proved by sterilising the liquid by heat, or by the addition of chloroform, or sulphate of copper, when the nitrate of potash under-

went no alteration. The organisms concerned seem to be anaerobic; if they were cultivated in a large surface, and in contact with air, either they did not produce the effect at all, or their action was considerably lessened. The temperature most favourable to the process was found to be between 35° and 40° C. The presence of organic matters is absolutely necessary, but all organic substances are not equally suitable. Of those which have been tried, olive oil, and oil of sweet almonds, glycerine, glycol, sugar, alcohols of the fatty series, tartrates, &c., the best results were given by sugar, ordinary alcohol, and propylic alcohol. For instance, three or four drops of the latter, added to a liquid in which the denitrification was suspended, at once renewed the process. The oils became rapidly saponified. Considerable interest attaches to the action of two substances, carbolic acid and salicylic acid. Employed in the proportions usually considered to be antiseptic, and even in still larger quantities, they not only did not interfere with the growth and activity of the organisms, but were themselves destroyed with the nitrate, just as sugar or propylic alcohol would be. The destruction of carbolic acid by organisms has been already observed by Muntz, even when it amounts to several grammes per litre. Thus under favourable circumstances the process of the destruction of nitrates presents all the characters of an energetic fermentation. It is accompanied by a rapid growth of organisms, and an abundant liberation of gas. This gas consists of pure nitrogen, and represents a considerable proportion of that contained in the nitrate. The rest probably forms ammonia. The oxygen forms carbonic acid, which remains combined in the liquid. The influence of the organic matter is thus to cause the products of the fermentation of the nitrate to enter into new combinations. Other nitrates behave in the same manner as the nitrate of potash.

#### ALCOHOL IN THE ST. PANCRAS WORKHOUSE.

DR. DUNLOP, medical officer to the St. Pancras workhouse, has had his attention called by a resolution of the guardians "to the present large consumption of beer, wine, and spirits in the workhouse, and to the question whether so large a consumption is necessary for medical purposes." He replies in an able letter, which is at present under the consideration of the Board. There is no doubt he takes a large view of the medical uses of alcohol—probably rather a larger one than is at present generally held. His therapeutical estimate of alcohol reminds us more of what we used to read in Dr. Todd's lectures twenty years ago than of the guarded and stinted admissions as to its occasional indispensableness which characterise the expression of present medical doctrine. He admits the deplorable mischief done by alcohol and says, "Alcoholic liquors are a most prolific source of pauperism, disease, and crime"; but with what seems a sort of homoeopathic tendency, he thinks that a little alcohol is good for almost all sorts and conditions of paupers. It affords the greatest relief to the aged suffering from chronic disease; it is invaluable in lying-in wards; it is of the greatest service in the natural and artificial feeding of the insane; it is equally useful in the collapsed and in the convalescent stages of acute disease, especially pneumonia; in the case of scrofulous children port wine is a valuable agent; and in the diarrhoea and sickness of such children iced brandy will often avail when nothing else will. "As regards the prescription of porter, I look upon it both as an article of diet and as a fillip to the appetites of the aged sick and poor, to whom it is alone prescribed." This is undoubtedly hard doctrine for teetotal guardians. We will admit that it implies an estimate of the use of alcohol at all ages of pauperism, which in a workhouse infirmary, where any reasonable nourishment can be obtained—we think open to criticism alike from the scientific, the moral, and the ratepaying point of view. But Dr. Dunlop's letter is that of an earnest and intelligent

medical officer, and the guardians will find it best to do no more than raise the question to such an officer and leave him to grapple with it as he can.

### REDUCTION OF DISLOCATIONS OF THE SHOULDER.

THE number of modes of reducing dislocations of the shoulder shows that the best plan is yet generally unknown. A valuable paper on this subject was read by M. Kocher at the meeting of the International Congress in London. Referring only to the subcoracoid form of dislocation, he asserts that the aim of the surgeon should be to open out the rent in the capsule, and to relax the parts of the capsule which are untorn but tightly stretched by the false position of the head of the humerus. The rent in the capsule is on the inner side of it; the most tense part is the upper portion where it is thickened by the coraco-humeral band; the lower part of the capsule is also tense. Kocher asserts that by rotating the arm outwards the top of the capsule is itself rotated out and the rent rendered patent. If now the arm be advanced in the vertical median plane, the upper part of the capsule is relaxed, and the head of the bone, being prevented passing forwards by the lower fibres of the capsule, enters the glenoid fossa. He accordingly directs that for the reduction of this dislocation the following manipulation should be practised. The patient should be seated, with the surgeon on his left hand. The elbow-joint is first to be flexed to a right angle, and the joint firmly pressed against the side of the chest; then while holding the elbow in contact with the body the arm is to be slowly, gently, and steadily rotated out until firm resistance is encountered; then maintaining this rotation the arm is to be raised forwards and a little in, and lastly to be rotated in and the hand brought towards the opposite shoulder. It is stated that there is no need for anaesthetics when this manipulation is employed. This method, which has great advantages over those in common use in this country, is stated by M. Ceppi (*Revue de Chirurgie*) to be especially valuable in old dislocations, enabling them to be reduced often without any force and without anaesthetics. M. Kocher has succeeded in twelve cases of dislocations, varying from three weeks to four months old. In one case, where the bone had been displaced for eight weeks, he fractured the shaft of the humerus in attempting the reduction, and six weeks later, when the bone was united, failed again. This patient was seventy years of age. We believe that this method of reduction is worthy of far more attention than it has yet received.

### PROVIDENT DISPENSARIES AND AID FROM WITHOUT.

MR. VACHER, in speaking with satisfaction of the progress of the West Cheshire Provident Dispensary, said they were still to some extent dependent on aid from without. His words are worthy of attention when provident dispensaries are so lauded as the schools of providence and self-help. He said:—"I have referred to the portion of the income contributed by provident members rather than to the whole income, as the only right way of gauging success. I cannot, of course, say that we are independent of aid from without; nor can I hold out a hope that in course of time we shall be. Our experience has taught us that if the doctors are paid half the working men's subscriptions, the portion they are entitled to by the rules, the remaining half is just about sufficient to provide first-class drugs, the dispenser's salary, and our rent. Other incidental expenses, so far as we now see, must always be provided for in some other way. I may say that our experience is not exceptional. The committees of provident dispensaries all over the country have come to

the same conclusion—namely, that help of some sort over and above the working-men's contributions is needed. However, many good friends have come forward to help us in the past, and I do not doubt will again." Such a representation of the system of provident dispensaries shows that they are not by any means perfect institutions, either from an economic or professional point of view. They pay their medical officers very inadequately—less than many good clubs do; and, secondly, they are dependent on charitable assistance. The families of working men who are fairly well employed should have no difficulty in paying a medical man two guineas a year, in monthly or quarterly instalments. This is much less than they spend on beer, and much less than many men who love their families, and appreciate their doctor, spend for medical services. We fear that the provident dispensaries are being so used as to lower the public sense of the value of medical service.

### THE DEATH OF MR. BENJAMIN FIELD.

IT ought to be understood by patients who suffer from heart disease, and by their friends, that it is unsafe for them to make any special exertion, particularly of such a nature as to excite the heart to unusual activity. It is not necessary that those who are affected with cardiac maladies should have their lives embittered by continuous apprehensions, but they would do wisely to be warned that certain procedures are perilous, and to avoid them, without reference to feelings and inclinations. The dangers attendant on organic disease of the heart are physical, it may be said mechanical, and therefore they are, in a sense, almost always avoidable. The cracked pitcher will go for years to the well, and serve all legitimate purposes, if only it be borne in mind that it is cracked, and it is neither subjected to a special strain nor roughly handled. Possibly this might be more clearly understood by the public than it would seem to be, judging from the deaths from mismanagement, which are unhappily many and inexpressibly sad.

### CROWDING ON THE UNDERGROUND RAILWAY.

THE crowding on the metropolitan and suburban lines of railway is simply disgraceful. Can nothing be done to put a stop to this practice? It is vain to expect the Companies to mend matters. They are chiefly intent on keeping down their expenses and raising their dividends. Unless the Board of Trade or some other authority can see its way to the appointment of a few travelling inspectors, who shall not wear uniform and shall take tickets as ordinary passengers, no reform can be anticipated. The matter is clearly one that requires attention. The overcrowding of railway carriages—to the extent sometimes of crowding twenty into the space intended for ten—is not simply an annoyance; it involves very serious peril to public health, and obviously more than doubles the risk to life and limb to which each passenger will be exposed in the event of an accident occurring to a train thus crowded.

### EXTRAS FOR FRACTURE UNDER THE POOR LAW.

THE County Court judgment in the case of *Grubb v. the Chesterton Board of Guardians* will be read with satisfaction. The Board disputed the payment of £3 for the treatment of a fractured leg by Mr. Grubb on grounds set forth in the report in another column. Dr. Rogers was subpoenaed as representing the Poor Law Medical Officers' Association. Not only was the verdict strongly in favour of the surgeon claiming the ordinary fee, but the expenses of witnesses were allowed. We cannot but think that it would be well if the parsimoniousness of boards of guardians in the matter of medical fees were thus exposed a little more frequently.

## THE MIDLAND RAILWAY TRAGEDY.

THE painful feeling general throughout the country regarding the new danger to railway travellers, revealed by the sad calamity of Sunday morning, will be intensified to the profession from the fact that the first victim is taken from our ranks. Hitherto such stories have come from the far West, the natural home of the sensational and of new horrors; but even there it would be difficult to find a similar sad scene to that enacted on our most luxurious railway route, as in America the construction of the carriages is such as to allow of free intercourse between all parts of the train, while we have but copied the travelling palaces, and placed them in isolated positions, with only an imperfect signalling arrangement. It is impossible to conceive a more tragic situation than that in which the occupants of the doomed Pullman found themselves placed when roused by the attendant; and on an occasion like this, unless the communication with the engine-driver can be effected simply and rapidly, it might as well be non-existent. Time after time the method now in use has been complained of as inefficient, and the present sad fatality may arouse the directors of the various railways to the necessity of better arrangements. The Midland Railway Company has always been governed by men who were in every way willing to ensure the safety and comfort of travellers by their route, and the public will look to them to adopt such means as may minimise the danger should the startling cry of fire be again raised in any of their carriages.

## SIR THOMAS WATSON, BART.

THE chief change in Sir Thomas Watson's condition during the past week has been a gradually increasing weakness, with little or no alteration in the paralytic symptom. Since Thursday, the 26th ult., he has been confined to bed. The utmost amount of nourishment that he can be induced to take does not exceed a pint of milk in the twenty-four hours. He is in full possession of his mental faculties, and happily suffers no pain.

## CYSTICERCI AND TAPEWORM.

THE coexistence of cysticerci and *tæniæ* in the same subject at the same time has been very rarely noted. An instance was described by MM. Rathery and Sevestre at a recent meeting of the Société Médicale des Hôpitaux. The existence of the tapeworm (*tænia solium*) was not suspected until it was found post mortem in the small intestine. The patient died from heart disease. Fifteen or sixteen cysts were found in different parts of the body. All were situated in the substance of the muscles. The existence of heart disease, and of hæmaturia shortly before death, had led to a suspicion that some of the cysticerci might be located in the kidneys or heart, but the autopsy showed that all the viscera were free.

## THE PECULIAR PEOPLE.

ANOTHER little victim of the fanatical prejudice of the Peculiar People is reported in the *Chelmsford Chronicle* of October 27th—a child at Southend burnt by the flames of a petroleum lamp. The mother and father were "peculiar" in their religious and medical views, and, instead of calling in a doctor, called in an old woman who applied oil, and the elders of the church who "prayed over the child and anointed it with oil." Notwithstanding, it died a week after the burn. The coroner remarked on the impropriety of neglecting to seek medical aid, and pointed out that people had been tried for manslaughter in such cases. Mr. Jones gave it as his opinion that life might have been saved or prolonged by medical attention, but the jury contented

themselves with a verdict of accidental death. It is more easy to complain of this verdict than to see how any amount of punishment or imprisonment would help children who have the misfortune to have such "peculiar" parents.

## THE LATE MR. GEORGE CRITCHETT.

WE regret to have to announce the death of Mr. Critchett, the oculist, on Wednesday last, at his residence in Harley-street. Though Mr. Critchett had been seriously ill and confined to his rooms for some weeks, his medical advisers were not without hope of his recovery until Sunday last. His powers from that time steadily failed. We hope next week to give a fuller notice of Mr. Critchett's work.

## GLASGOW DRAFT POLICE BILL.

THE Faculty of Physicians and Surgeons met on Monday last to discuss this measure, with the result of bringing out an entire unanimity of feeling in opposition to the compulsory notification clauses of the Bill, in so far as they lay on the medical attendant the onus of reporting infectious diseases to the sanitary authorities; and a resolution was unanimously adopted recommending rather that the medical attendant should be asked to certify the case to the householder or guardian of the patient, and that this guardian should be bound to report to the authorities. A committee was appointed to draw up a memorial to the Town Council urging this view of the matter.

MOST neurological workers on this side of the Atlantic are familiar with the name and writings of Dr. Seguin of New York, and will learn with almost personal sorrow the terrible calamity which has befallen him—an event not often equalled in the horrors of insane homicide, and probably altogether without parallel in its signally pathetic circumstances. On Wednesday last Mrs. Seguin tied the hands of her three young children behind their backs, blindfolded them, and then shot them through the head, apparently while playing "blind man's buff" in an empty room in the top of the house. She then shot herself also through the head. Mother and children were all dead when the deed was discovered. Three pistols were found in the room. She had been depressed for several days. The case is a terrible illustration of the insidious manner in which homicidal and suicidal tendencies come on in melancholia, since an experienced specialist like Dr. Seguin cannot have suspected their existence even in the person most near to him.

IN a brochure just published, Mr. Chas. J. Hancock describes the condition of *anæmia*, followed by general dropsy, so prevalent among natives of tropical countries. His handbook deals solely with the disease as seen among coolies, and contains much that is of practical value in the treatment of the sick. Originally addressed in the form of a letter to certain proprietors and managers of tea estates, it is now reproduced in a pamphlet form, and should prove useful to practitioners in the colonies, where coolie labour is much employed.

ADVICES from Cape Town, dated Oct. 11th, state the epidemic of small-pox is still steadily declining, and the Mayor, at the last meeting of the Town Council, said that two medical men would be sufficient to attend to the cases now existing in Cape Town. At Durban, Natal, the Government is building a small-pox hospital on the Bluff. It is thought that about thirty beds will be sufficient. The hospital is being built only in case the disease should break out in the town.

THE London Memorial Brass Committee have decided to hand over the surplus money subscribed to Mr. Landon's Memorial to the Fund now being raised for a Memorial to the Officers of the Army Medical Department who fell in the recent campaigns in Afghanistan and South Africa. His Memorial will, of course, include the name of Mr. Landon.

THE yellow fever epidemic in Florida still rages with unabated virulence, and is spreading northwards and westwards. At Pensacola the total number of cases reported up to October 16th was 1677. Many of the medical attendants have themselves been attacked, and one of them, Dr. S. C. Lacintyre, has succumbed to the disease.

JAMES ANDERSON, M.D., C.M., M.R.C.P. Lond., Assistant-Physician to the Victoria Park Chest Hospital, Junior Demonstrator of Anatomy in the London Hospital, has been appointed Examiner in Anatomy at the Royal College of Physicians of London.

PROFESSOR NOTHNAGEL was warmly welcomed by the students on the occasion of his first clinical lecture since his appointment to the Vienna chair. He prefaced his lecture by a short address, in which he alluded to his predecessors Duchek and Skoda, and spoke of the methods of clinical study.

M. LELOIR, relating in last week's *Progrès Médical* his experience of the system of continuous baths in the treatment of skin disease as carried out in Vienna, reports very favourably on the procedure, and advocates its introduction into the St. Louis Hospital at Paris.

It is announced that Major-General Sir Evelyn Wood, V.C., K.C.B., has been selected to serve as a member of the Committee appointed to inquire into the alleged shortcomings of the Army Medical Service in Egypt. The Committee met on Wednesday at the War Office.

THE Bangor fever outbreak has virtually subsided. Nearly all the existing cases are in a convalescent state, and the use of the hospital tents in the Bishop's Park is to be discontinued.

THE fever epidemic which has been prevalent in Johnstone, N.B., for the past six weeks is still exciting considerable alarm. There is some uncertainty as to whether the fever is even yet showing any signs of abatement.

DR. J. I. BANKS has been elected a representative of the Royal University of Ireland on the General Medical Council for three years from January next.

THE Dictionary of Medicine, by various writers, under the editorship of Dr. Quain, has just been issued by Messrs. Longman and Co.

SIR JAMES PAGET, Bart., has fixed Wednesday, the 13th of December, for the delivery of the first Bradshawe Lecture at the Royal College of Surgeons.

WE regret to learn from the *Daily Telegraph and Deccan Herald* of Oct. 5th that Surgeon-General Beatty, of the Bombay Army, has sustained a severe fracture of the leg.

DR. ROBERT BARNES has been elected an Honorary Fellow of the Obstetrical Society of Edinburgh.

## Medical Societies.

### CLINICAL SOCIETY OF LONDON.

*Bullet Wound of Lower Jaw.—Hæmorrhage after Scarlatina, Ligation of Common Carotid Artery.—Bilharzia hæmatobia.*

AN ordinary meeting of the Clinical Society of London was held on Friday, Oct. 27th, J. Lister, Esq., F.R.S., in the chair. Mr. Lister stated that he had received a letter from M. Ollier of Lyons, expressing his high sense of the honour conferred upon him in electing him an honorary member of the Society. The three communications read were all of them of considerable interest, and that of Dr. Mahomed and Mr. Pepper gave rise to a lively discussion.

MR. W. J. WALSHAM narrated a case of Gunshot Injury of the Lower Jaw. H. W—, a woman twenty years of age, was admitted into the Metropolitan Free Hospital, under Mr. Walsham's care, on July 16th, having been shot with a revolver. The wound was situated about an inch above the angle of the jaw, and passed in a direction backwards, inwards, and upwards. The wound was enlarged, and the jaw was found perforated; the finger could be passed in as far as the first interphalangeal joint, but neither with it nor with a probe could the bullet be felt. On examining the mouth a slight fulness above the right tonsil was seen, but there was no wound nor definite indication of the bullet. Considering the importance of the structures among which the bullet was evidently imbedded it was not deemed prudent to endeavour to extract it. The patient was quieted by opiates, and water dressing was applied to the wound. Considerable swelling about the angle of the jaw in the region of the tonsil supervened, accompanied by a constant dribbling of saliva from the mouth. On July 25th a spiculum of bone, accompanied by a small part of the crown of the wisdom tooth, and on the 26th the bullet with the remainder of the wisdom tooth imbedded in it, were discharged. The patient progressed satisfactorily, and left the hospital on Aug. 16th with the wound nearly healed. Mr. Walsham remarked that the chief point of interest, in addition to others, lay in the question of treatment. Three distinct courses presented themselves: to attempt the extraction of the bullet through the external wound; to cut down upon it, and remove it through the mouth; or to leave it, in the hope that it might escape spontaneously or become encysted. The objections to the first were that a large portion of the jaw would have to be cut away to obtain room for the necessary manipulations, that the exact situation of the bullet was not known, and that there would have been considerable risk of wounding some of the large vessels and nerves between which the bullet had evidently passed. Against the plan of removing it through the mouth the fulness about the tonsil did not seem to point sufficiently clearly to that being the situation of the bullet to justify an incision in such a dangerous region. The course pursued in face of these considerations was to leave the bullet to come away spontaneously.—MR. LISTER said the case was interesting as an example of perforation of the lower jaw without fracture, which was remarkable in a bone of such density. He quite agreed that it was right to have left the bullet alone. The bullet itself was not so much a source of evil—not so mischievous as attempts to remove it. But as there was no evidence of communication with the mouth, the case admitted of strict antiseptic treatment, and he thought it would have been wise to have tried to keep the wound aseptic; if this attempt had succeeded all danger of secondary hæmorrhage and deep suppuration would have been avoided. Happily, however, these did not occur.—MR. WALSHAM replied that he had thought of this line of treatment, but that as the bullet had carried in septic materials, he considered it would have been difficult to render the wound aseptic, especially as he did not know the course of the bullet.

DR. MAHOMED and MR. PEPPER read notes of a case on which Mr. A. J. Pepper had successfully tied the common carotid artery for severe bleeding from the throat after an attack of scarlet fever. C. W—, aged thirty, was admitted into the Fever Hospital, under the care of Dr. Mahomed, on Jan. 2nd, 1882, suffering from scarlet fever, which ran a simple course with ordinary convalescence until

Feb. 22nd, when the patient shivered and complained of sore-throat; temperature 101.2° F. On the next morning the uvula was large and translucent, and there were redness and swelling of the palate. On the 24th he complained of great difficulty in swallowing and throbbing of the left side of the throat. Two hæmorrhagic patches had appeared at the junction of the hard and soft palates with a large gelatinous bleb on the left side. Three hours later the throat, especially the left side, became rapidly swollen, accompanied by a feeling of suffocation; soon after the patient brought up a considerable quantity of blood; the swelling and difficulty of breathing subsided, at the same time the hoarseness passed quite suddenly into complete aphonia, which persisted. The alternate enlargement of the neck, hæmorrhage, and subsidence of the swelling were repeated several times until the morning of the 27th, when the patient's condition became critical, he having lost forty ounces of blood in all, and there was no sign of arrest of the hæmorrhage; there was a considerable bulging of the left side of the neck, marked dyspnoea, and aphonia. At a consultation between Dr. Mahomed and Mr. Pepper it was decided to ligature the left common carotid artery, as it was thought dangerous to cut into the post-pharyngeal abscess. The patient was put under chloroform and the artery tied by Mr. Pepper at the upper border of the omo-hyoid muscle. Considerable difficulty was caused by the greatly distended state of the veins; carbolic catgut was used, and the operation performed antiseptically. For a time respiration threatened to fail, but the man rallied in three or four hours. Soon after the operation he brought up six ounces of pus, and there was a corresponding diminution of the swelling. The temperature at once became normal, and the wound healed rapidly.—April 7th: Numbness of skin corresponding to distribution of superficial cervical nerve; partial aphonia; fixation of left vocal cord; general health good.—Dr. MAHOMED remarked that secondary sore-throat after scarlatina was not uncommon, having occurred fifty-seven times out of 3957 consecutive cases treated during the last ten years at the Fever Hospital. It resembled the condition of the throat seen in the primary attack. He considered it to be a modified second attack of the disease dependent upon concentration of the poison, for it was most frequent when the wards were overcrowded and badly ventilated. It had never been fatal at the hospital. Complete second attacks, with rash, sore-throat, and fever, occurred in twenty-nine cases out of 3957; all recovered save one, who died from other complications. Hæmorrhage from the throat was a rare but very dangerous complication. It might occur during the primary or secondary throat affection. It resulted either from sloughing of the soft palate, or, as in this case, from opening of a vessel into an abscess. There had been six cases at the Fever Hospital in ten years, and all the severe ones, except this case, had been fatal. The ligature of the artery appeared to exert a very beneficial action over the inflammation, which recovered most rapidly and completely.—Mr. HOWARD MARSH said that at St. Bartholomew's Hospital there had been within the last few years several cases of abscesses ulcerating into large arteries. One of these was a case of unopened psoas abscess, which suddenly became very distended, and post mortem it was found that the aorta had given way into the abscess. Another case was one in which Mr. Marrant Baker tied the common iliac artery for hæmorrhage which occurred on opening a gluteal abscess, and afterwards a free opening of the gluteal artery into the abscess was found. In another case of an open ischio-rectal abscess free hæmorrhage occurred from the internal pudic artery; and, in yet another, hæmorrhage occurred into a perineal abscess; both these latter were successfully treated by pressure. In a case of abscess in the neck in which hæmorrhage occurred, ligature of the common carotid artery did not control the bleeding. He referred to a case in St. George's Hospital where, for a wound of a large artery high up in the neck, the common carotid was successfully tied lower down.—Dr. DYCE DUCKWORTH thought this case unique; in his experience all cases of such hæmorrhage had been fatal, the rush of blood had been sudden and profuse.—Mr. CRIPPS referred to his paper read at the Medico-Chirurgical Society on the treatment of hæmorrhage from punctured wounds in the throat and neck. He thought that ligature of the common carotid artery was a very fatal operation—56 per cent. of deaths,—and was more fatal when performed from hæmorrhage than from aneurism. In 28 per cent. of the deaths the fatal result occurred from brain symptoms, and in 28 per cent. from re-

current hæmorrhage. In these cases he thought the external carotid artery was the one to be tied, as then the brain was not deprived of blood. Recurrent hæmorrhage occurred owing to the free anastomoses of the vessels, and especially owing to blood coming from the circle of Willis, and passing over the bifurcation of the common carotid into the external carotid. With extreme rarity had the bleeding artery been shown to be the internal carotid in these cases, but in nearly all dissected cases a branch of the external carotid artery was wounded, and to tie this latter vessel was the right line of practice. This operation was not liable to be followed by secondary hæmorrhage, less liable than the ligature of any other deep artery, and the artery was easily found. If the blood actually came from the internal carotid artery, he thought there would be no time for any operation at all.—Mr. RICKMAN GODLEE spoke of a very chronic case of psoas abscess with disease of dorsal vertebra. When dilating two sinuses in the groin, the external iliac artery was felt between them, and a few days ago fatal hæmorrhage occurred from the common iliac artery.—Mr. JAMES BLACK referred to a case of quinsy in St. Thomas's Hospital, in which severe hæmorrhage occurred; Mr. Pitts tied the common carotid artery, the bleeding recurred two days later, and was then fatal, and at the autopsy the internal carotid artery was seen to be opened by ulceration.—Mr. A. BARKER asked if the bleeding spot in the throat was seen.—Mr. PEPPER: No.—Mr. LISTER said the case was one of great interest. Where possible it was best to treat the bleeding point rather than the main arterial trunk. Here to get at the bleeding point was impossible. From the result he thought the bleeding artery must have been small, if the blood did not actually come from the walls of the abscess cavity from tension. He had seen cases of abscess in which hæmorrhage occurred from the disturbance produced by tension; and in this case he thought the hæmorrhage might possibly have been stopped by a free incision into the abscess. He agreed with Mr. Cripps that in these cases it must be a branch of the external carotid that was wounded, as a wound of the internal carotid would certainly be rapidly fatal.—Mr. HOWARD MARSH's cases were very interesting, for in the majority of cases of abscesses ulcerating into large arteries the artery gives way after the abscess had been opened, and in support of this he referred to Liston's celebrated case and to the fact that at that time surgeons would scarcely admit the possibility of an artery being opened up by an unopened abscess.—Mr. PEPPER thought that the blood in such cases of abscess near the tonsil probably came from the ascending pharyngeal artery, which arises close to the bifurcation of the common carotid artery, and which would not be affected by ligature of the external carotid. Another reason for his line of action was, that an incision high enough to lay bare the external carotid artery would have opened up the sloughing cavity of the abscess and have prevented the operation being aseptic. He thought the large amount of the hæmorrhage showed that the blood came from a good-sized artery.—Dr. MAHOMED said that the position of the ligature was most carefully considered, and he thought to ligature the external carotid would have been attended with great risk. He remarked upon the great rarity of cases in which hæmorrhage occurred from arteries laid bare by pulmonary abscesses. A short time ago he had under his care for a time a case of splenic leucæmia; there was a large fluctuating swelling over the buttock, which was thought to contain pus. Mr. Symonds opened it, and it proved to be a diffuse hæmorrhage into the cellular tissue, and there was the greatest difficulty in controlling the hæmorrhage, which was only stopped by laying the cavity open very freely and plugging it firmly from the bottom.

Dr. RADCLIFFE CROCKER showed the Ova and Embryo of Bilharzia Hæmatobia, and related a case of hæmaturia produced by that parasite which came under the care of Dr. George Bird at the beginning of the year. The patient was a boy at school, aged thirteen years, who was born in the Orange Free State, but appeared to have caught the disease in Natal, where he passed blood both by the urethra and bowel, and had been treated for dysentery. A few months after his arrival in England hæmaturia recurred in considerable quantity, and produced so much dysuria as to necessitate the use of the catheter, and a small clot of blood which clung to the eye of the catheter having been removed by Dr. Crocker, the characteristic ova of bilharzia hæmatobia were discovered. All troublesome symptoms soon disappeared, and, with the exception of slight anæmia, the boy seemed to

be in good health, nevertheless the parasites are still present, and ova and a little blood were found in all three specimens of urine passed at different times in the day on Oct. 4th. The spine on the ovum was always terminal, as is usually the case in those discharged from the veins of the bladder; and the head of the embryo showed no special preference for the head end of the ovum. As the disease usually gets well spontaneously after puberty, no local treatment for the destruction of the parent distoma had been employed. In blood taken from the finger at night no filariae were discovered.—Mr. PEPPER asked how injecting fluid into the bladder would succeed in killing the parasites.—Dr. CROCKER said that was the treatment adopted by Dr. James Allen of Natal, who says he has met with great success from it. In most cases the parasites are found only in the veins of the bladder, although in other cases, no doubt, they were present higher up the urinary tract. Dr. Allen had spoken favourably also of the internal administration of santonin.

## MEDICAL SOCIETY OF LONDON.

### *Chancre on the Cheek; Cardiac Aneurism; Experience of 600 Cases of Diabetes.*

At the meeting of this Society, held on the 30th ult., F. Mason, Esq., President, in the chair,

Mr. PEARCE GOULD showed a man with a Hunterian Chancre on his Cheek. The patient, a young married man, came to the Westminster Hospital ten days previously. The chancre was as large as a halfpenny piece, defined and moderately indurated, with an abraded surface. There was one enlarged gland over the parotid gland and several below the jaw. There was also an abundant roseolous rash over the trunk, and very slight sore-throat. The chancre had been noticed altogether two months, and was now rapidly improving under mercurial treatment. The only clue to the mode of infection was the fact that he was in the habit of "larking" and taking his meals with a cousin who was suffering at the time from a severe attack of syphilis.—The PRESIDENT mentioned similar cases which he had recorded before the Society and in the St. Thomas's Hospital Reports, and laid stress upon the necessity for accurate diagnosis, as in some cases operations had been undertaken for the removal of chancres of the lip mistaken for cancer.—Mr. ROYES BELL referred to two cases, and Mr. E. OWEN to another, the latter remarking on the size and spongy character of the sore in Mr. Gould's case—similar to the chancres that sometimes occur on the fingers of medical men.—The PRESIDENT remarked upon the comparative rarity with which medical men were inoculated, seeing the risk they constantly ran in examining cases of syphilis.—Mr. GOULD, in reply, said he had seen a similar sore over the malar bone of a young girl communicated by a kiss from an infected person: also another in a girl six years of age. He related a case which he saw last week, where there appeared conclusive evidence of indirect inoculation through a w.c.

Dr. ISAMBARD OWEN showed two specimens of Cardiac Aneurism from the post-mortem room of St. George's Hospital. In both, the thinning of the wall affected the apical half of the left ventricle. Of one only, in which dilatation of the thinned cavity was not very marked, were clinical details available. This patient was aged sixty-one; the symptoms—short breath, cough, palpitation, and pain in the left side, had lasted seven years. The apex beat on the fifth space just inside the nipple line. The cardiac sounds were weak and both reduplicated; the pulse weak and dicrotous. There was no murmur. The lungs were very emphysematous, the aorta very atheromatous, and the kidneys granular. The second patient was seventy years of age, and was brought in dead. The kidneys were granular, and the cerebral and iliac arteries atheromatous.

Dr. SEDGWICK read a paper communicated by Dr. R. Schmitz, of Neuenahr and San Remo, entitled "My Experiences of 600 Cases of Diabetes." Of this number 407 were males, and 193 females; 30 were below twenty years of age, 56 between twenty and thirty years, 80 above sixty, and 434 between thirty and sixty years. The fact that violent emotion, mental anxiety, excess of saccharine diet produce diabetes only in some persons was held to prove that there is a diabetic disposition, which is usually transmissible by heredity, and may be manifested in a family as diabetes, and also as psychoses, and perhaps as tuberculosis. A family tendency to diabetes occurred in 243 cases, to psychoses in

96, and to tuberculosis in 42 out of the 600 cases. A large proportion—viz., 93 cases—occurred in Jews. In 8 cases both husband and wife were suffering from diabetes at the same time. In 183 cases mental disturbance of some kind appeared as the exciting cause, in 45 cases gout, and in 22 the exhaustion consequent on severe disease. The urine was mostly clear, of a pale or light yellow colour, usually very acid, rarely neutral, very seldom alkaline; sp. gr. 1025 to 1030, never above 1042, frequently as low as 1013 to 1015. The average daily amount was 2500 c.c. to 3500 c.c., in one case as much as 9000 c.c. and in 40 as little as 500 c.c. to 800 c.c., but in these latter cases there was profuse sweating. The day urine generally contained most sugar, especially that voided two or three hours after a meal; in some cases the night urine was the most saccharine. Mental exercise or anxiety notably increased the sugar, physical exertion rather diminishing it. The amount of sugar varied from 1 to 3 per cent. of the urine, rarely to 4, still more rarely to 5, very seldom to 6, and in only one case to 8 per cent. In some cases albumen was present to from 0.3 to 0.1 per cent., its amount often varying in inverse ratio to the amount of sugar. The albumen was increased by exhaustion and severe exercise, and after fasting, but decreased after a meal. After the disappearance of sugar there was often a material increase in phosphates, and in some a considerable amount of oxalates; in four cases hippuric acid was present. In two cases there was a substance, probably a modification of uric acid, which reduces copper in the same way as sugar, the practical importance of which was illustrated by the case of a physician who found that the "sugar test" increased when put on anti-diabetic diet. The polariscope and fermentation test eventually solved the problem, and the substance was found to disappear from the urine during the use of a mixed diet, to reappear when flesh was freely eaten. Dryness of the skin goes with increased quantity of urine and emaciation. If the skin acts well there is never extreme emaciation. In 35 cases there was distinct obesity. The weakness and prostration are due to a special pathological process in the muscles; and to this muscular degeneration are owing disorders of visual accommodation, constipation, and many of the cardiac symptoms terminating in sudden death. The weak cardiac muscle caused in many cases an irregular, feeble pulse, and a very indistinct first sound, and in some violent exercise was followed by serious symptoms, as nausea, vomiting, drowsiness, great prostration, sometimes convulsions, temporary paralysis, and loss of consciousness. In these cases it is necessary to forbid the upright posture for some time, and to administer stimulants freely. In four such cases death resulted, and in two others on their way from Neuenahr—one with extreme muscular degeneration, the other from rupture of the heart. Such cases are misnamed "diabetic coma." They are due to an exhausted heart, resulting in arterial anæmia, venous hyperæmia, and the consequent carbonæmia. They may be confounded with those cases of acute poisoning called acetonaemia, of which he had seen six cases, but in these the attack is sudden, and although there is nausea and drowsiness the pulse is regular, rapid, Cheyne-Stokes' respiration, fetid odour of breath, and from the beginning frequent paroxysms of abdominal pain, rousing them up at intervals from their state of somnolence. No sugar is passed during the attack, and free purgation with castor oil, resulting in the passage of dark-coloured offensive motion, was of great service. If not relieved by purgation death occurred in coma mostly; in two cases in convulsions. Whether due to acetone or not, the author is convinced there are cases of acute poisoning from a very noxious substance developed from the decomposition of the sugar in the intestines. There are two forms of hunger—one due to excessive tissue change, the other a true neurosis, accompanied by occipital pain, and relieved by codeia or morphia, with potassium bromide. Some diabetics have an unaccountable desire for sugar. Total loss of appetite is very rare. The thirst is a result of the polyuria, not of the glycosuria. The sour alcoholic smell—termed by some acetone smell—is characteristic, and, except in the cases of acetonaemia, is proportioned to the amount of sugar in the urine. Looseness and falling out of the teeth is an early symptom, often accompanied by a spongy state of the gums; this is much benefited by rubbing the gums several times a day with a slice of lemon and the use of a gargle of sage and cochlearia. Constipation, alternating with diarrhoea, is frequent, depending not on the use of animal food but on atony of the muscular coat of the digestive canal. The diarrhoea, as a rule, begins in the night, after a continu-

ance of constipation, the faeces are fetid, watery and grey in colour, and the attack, invariably followed by great diminution in the amount of sugar, is believed by the author to be due to fermentation of sugar in the small intestine. Castor oil should be given, and failing relief, should be followed by bismuth or tannin; opium being objectionable. Neuroses of various kinds are by no means uncommon. Cramps in the calf of the leg are frequent, and when long-continued are little influenced by local narcotics. Crural neuralgia is common; sciatic and lumbar neuralgia more rare; cervico-occipital neuralgia occasionally, and in one case mastodynia (in a man aged seventy-five). Salicylate of soda and codeia are of most use for the relief of pain. The pruritus pudendi and balanitis may be neurotic, as well as directly caused by the sugar; a lotion of salicylic acid gave most relief. Tuberculosis was developed in the course of the disease in twenty-six cases, and was persisting in fifteen others. Impotence or diminished sexual desire was common, but in twelve patients there was increase of venereal desire. Dimness of vision is partly due to turbidity of lens, partly to loss of accommodation. Three cases of cataract occurred; they were operated on and did well. Boils were very common, caused by the nutritive disturbances of the skin. Several cases occurred in which the sugar permanently disappeared; this and the more common result of treatment—a great diminution in the quantity—are more often met with in those attacked in middle age than in youth, and much more often when the disease is recent than when it was of long standing. Much depends on the patient and his adherence to an anti-diabetic diet. When diabetes follows on disease of the central nervous system, tuberculosis, heart affections, or other organic mischief, the prognosis is bad; less so when grief, anxiety, or mental fatigue has been the cause; and still less unfavourable when excess of saccharine food has produced the malady. But the most favourable prognosis is to be given when goat is the origin of the diabetes, and also in diabetes arising during convalescence from typhus.—Dr. JAGIELSKI distinguished two groups of prominent symptoms—the neurotic and the digestive, and guided his treatment by the respective prominence of these groups. The paper did not state to what extent the use of the Neuenahr water entered into Dr. Schmitz's treatment. He deprecated a too rigid diet, and said that with the koumiss treatment he had been able, after a few weeks, to dispense with the absolute deprivation of starch and saccharine matters. Good results had been obtained also by lactic acid, butter-milk, and skim-milk.—Dr. GREEN thought the paper failed to discriminate the different varieties of diabetes, several distinct conditions being linked together by the one common feature of glycosuria.—Dr. SEDGWICK said it was clear that nearly all Dr. Schmitz's cases were at any rate not cases of temporary glycosuria.

#### MEDICAL OFFICERS OF HEALTH SOCIETY.

THE first meeting of the present session of this Society was held at 1, Adam-street, Adelphi, on Friday, October 20th, Dr. J. W. Tripe, President, in the chair.

The PRESIDENT read a paper entitled "On Some of the Relations of Meteorological Phenomena to Man," of which the following is an abstract. He stated that he did not propose to discuss the effects of all meteorological phenomena on man, as sufficient data were wanting for a complete inquiry, neither should he enter into the effects of climate, for that word included not only all the elements which are classed together under the term weather, but also the physical peculiarities of the locality in question, the nature of the soil, and the extent of forests and other vegetation which modify the climate of a place. He referred briefly to the part played by oceanic currents in making the climate of England temperate and pleasant, as he considered this was insufficiently recognised. The relations existing between man and variations of atmospheric pressure, temperature, and humidity were next discussed, together with their influence upon disease and death. Dr. Tripe said it was only at considerable elevations, such as eight thousand feet above the sea level, that the variations in the atmospheric pressure were appreciable. People were then affected with so-called "mountain sickness," which consisted of malaise, shortness of breath, palpitation of the heart, nausea, with more or less giddiness and noises in the ears. Some persons suffer more than others, but nearly all in time become acclimatised.

Aeronauts suffer from the same symptoms, showing that great muscular exertion is not the chief cause of the attack. Those who live on elevated mountain plateaux are observed to breathe more rapidly than those living at a lower elevation, their pulse increases in rapidity, and there is an increase in the evaporation from their skin and lungs, as well as a diminished secretion of urine. It is believed that all these symptoms are chiefly due to the diminution of oxygen in the air inspired, and consequently in the blood, and also to the imperfect exhalation of carbonic acid from the lungs, which, therefore, accumulates in the blood. The influence on man, and especially on invalids, of diminished atmospheric pressure, and of a lessened amount of oxygen inhaled, has been much considered of late, and while in some cases great benefit has been derived from a residence at high altitudes, in others change of residence has been of little or no use. Dr. Tripe considered that extreme cold also had something to do with the improvement manifested by phthisical patients. With regard to the effects of temperature on man, Dr. Tripe did not believe they depended so much on the mean temperature of the months and year as on the extent of range; for instance, when the day temperature is high and the night temperature comparatively low, the cold at night assists in procuring sleep and restoring the energy of the system which the heat had reduced. Variations in the pressure and temperature of the atmosphere exert a considerable effect on the circulation of air contained in the soil, or ground air, which consists of atmospheric air mixed with carbonic acid, marsh gas, and occasionally sulphuretted hydrogen. Rain also exerts a great influence on the ground water, and causes a rapid escape of air from the interstices of the soil. It is found that when the ground water is only five feet from the surface the locality is unhealthy, and also that a fluctuating level leads to ill-health amongst those residing on the spot. Outbreaks of typhoid fever have frequently occurred after heavy rain succeeding drought, which are believed to have originated from the infectious particles of typhoid excreta being washed into wells used for drinking. Damp soil is thought to be one cause of phthisis, and it has been shown that effective drainage of the land has caused a considerable diminution in the mortality from this disease. Wind influences to a great extent all meteorological phenomena, the humidity as well as the temperature of the air depending partly on the wind. Dr. Tripe pointed out that though much had been written concerning the effects of ozone on man, yet but little was really known about it. It is augmented by violent winds, and is met with chiefly at the seaside or in country places. There is but little doubt that it exercises an active oxidising action on the organic matter contained in the air, and is therefore absent in closely confined places where the air contains excess of organic matter. Dr. Tripe then alluded briefly to some of the individual diseases with which man is affected. He stated that it was only with great difficulty that reliable statistics on this point could be obtained, and that in an inquiry one or more elements must always be uniform and definite. If population be taken as a basis, corrections should be made for increase or decrease, and the condition of the population should also be considered. Care should be taken with regard to the initial periods of the inquiry and the time which should elapse after the occurrence of the weather discussed, and the registration of death. The number of meteorological elements to be embraced in the inquiry should also be decided. Dr. Tripe then referred to some papers already published by him on Medical Meteorology, in which he had stated the conclusions at which he arrived concerning the relations between the mortality from scarlet fever, lung diseases, diarrhoea, and meteorological phenomena. He believed that the periodical occurrence of epidemics did not depend on meteorological phenomena, but on the number of persons liable to the diseases living in the locality. In conclusion, Dr. Tripe made a few observations as to the temperature which induces the growth of bacteria so as to cause endemic or epidemic diseases, and also the influence of light on them, as illustrated by experiments made by Professor Tyndall and others.

On the motion of Dr. Bristowe and Dr. Stevenson a vote of thanks was unanimously accorded to the author of the paper, and the Society adjourned.

MEDICAL MAGISTRATE.—The name of Dr. W. W. Miller has been placed by the Lord Chancellor upon the Commission of the Peace for the County of Suffolk.

REPORT  
OF

## The Lancet Sanitary Commission

ON THE

## ROYAL COURTS OF JUSTICE.

THE erection of a great public building in this sanitary age is a fact of such importance that we feel sure we shall not be accused of stepping beyond our province in devoting a portion of our space this week to a description of that magnificent palace in the Strand which is henceforth to be the headquarters of the legal administration of this country. The first effect of the building upon the non-legal visitor is to awaken him to a sense of the exceeding complexity of the legal machine. The nineteen Courts, and the innumerable offices for officials, who are but little known beyond legal circles, are calculated to impress one with the fact that the Utopia of the philosophic Radical, in which society is to move smoothly under the instinctive guidance of natural laws, untrammelled by the clumsy enactments of man, is in the future immeasurably distant.

What should be the essential features of a building intended for the purpose for which the Royal Courts of Justice have been erected?

1. Simplicity of plan, so that those who have business here may find their way with ease to any desired point.

2. Separation of parts devoted to different purposes sufficient to avoid confusion, without unnecessarily increasing the space to be traversed in going from one part to another.

3. Quiet, so that the mind can think and the voice be heard.

4. Perfect acoustic qualities in the rooms devoted to the public administration of justice.

5. A maximum of light in all the rooms, for they are all devoted to work which involves much writing and much reading of crabbed text, and that often by men who have reached a time of life when eyesight has begun to fail.

6. The most perfect ventilation obtainable, in order that the best work may be got from the brain-cells of the workers with the least damage to health.

7. The building should be of a character to impress the mind with the pomp and majesty of the law.

Now it seems to us that if a result is desired for our public buildings which shall at all attain perfection, the way to proceed would be as follows:—First to ascertain from those who are to work in the building the amount of space required, and the purposes for which it is to be used. This being known and reduced to definite quantities by skilled persons, the second step should be to invite competition for the best plan, the question of style being kept rigidly in abeyance. The plan being selected with reference solely to its suitability and convenience, the third and final step should be a second competition for the most effective building upon the selected plan. With many of our public buildings the all-important point of plan has been entirely subsidiary to the question of style, and the prize has usually fallen to those architects who have furnished the most imposing elevation; and the elevation having been chosen, the building has been made to answer its purpose only in a haphazard way, and often by dint of constructing a puzzling labyrinth of dark passages and inconvenient rooms. There can be no doubt that this inversion of the "natural" order of procedure has been the cause of failure and inconvenience in many of our public buildings. What should we think of a tailor who, instead of making the clothes to fit the man, proposed by dint of sheer force to make his customer suit the clothes? We cannot help thinking that this inverted procedure has governed the erection of the new Law Courts, at least to some extent, for the number of staircases is simply bewildering, and the passages are for the most part (especially in the eastern block) so dark that artificial illumination will have to be resorted to for the greater part of the year even in the daytime. That men

advanced in years should have to mount some seventy or eighty steps in order to reach their official rooms is not creditable.

The artistic effect of the building appears to us to be all that can be desired. It is massive and imposing, and has a certain stern gracefulness which seems to tell of justice tempered by mercy, and this colossal work will be sufficient to place the name of Street quite on a level with the great artistic architects who have preceded him, with Inigo Jones, Wren, Barry, and Gilbert Scott. The style is Gothic, but of no one period, and this serves to give great variety to the outward effect. For solidity of construction it seems to us to equal the great buildings of the Middle Ages, and we trust that, unlike the Houses of Parliament, some generations may elapse before it is disfigured by the scaffoldings of tinkering masons. We are glad to see that an idea has been taken from Continental architects of providing in the original building for the necessity of repairs. The roofs, for instance, are everywhere studded by stout hooks, so that in the event of slates becoming loose it will be an easy matter to refix them, since a fir pole supported by two contiguous hooks will afford ample support for the slater or other workman.

But to come to details. The building is in two grand divisions. The western two-thirds of the building are devoted to the public administration of justice, while the eastern third, running parallel to Bell Yard, and extending from the Strand to Carey-street, is devoted to what we may call the more or less hidden machinery of the law, of which the public, other than litigants, takes little heed. A visit to this eastern part, a legal hive which has been in full work now for some time, is calculated to startle anyone who for the first time wanders among the hundreds of offices here congregated together. In the western part of the Royal Courts of Justice will be heard:—

"The sad-eyed justice, with his curly ham  
Delivering o'er to executors pale  
The lazy yawning drone";

while in the eastern part execution will be done, and the drawing, quartering, and disembowelling of unsuccessful suitors will be methodically carried out. Assuredly in letters of gold, should be written, over the main entrance of this department, the advice which Polonius tendered to his son:—

"Beware of entrance to a quarrel."

Entering from the Strand, through a highly ornamented porch and vestibule, we come into the great central hall, answering to Westminster Hall, and serving as a *Salle des pas perdus*. This hall is 232 feet long, 48 feet wide, and 80 feet high, and encloses rather more than 11,000 square feet of area, or about a quarter of an acre. The enclosing walls of this area are 560 feet in length. The decoration here is magnificent, and all the details, from the mosaic pavement to the elegant groined roof, reflect the artistic mind of the architect. This central hall gives access to the nineteen courts of justice. These courts are most of them approached by a vestibule building, and they are isolated buildings except where they are joined to the central hall on the one hand, and connected at their far ends by a building which affords a variety of accommodation for judges, barristers, juries, witnesses, and others concerned in the trials. This partial isolation of the courts admits of side-lighting as well as top-lighting, and a great deal of natural ventilation may be obtained in the summer by opening the windows. The deep, well-like spaces which are enclosed by contiguous courts are faced with white glazed brick in order that they may reflect as much light as possible. There is a certain similarity between the interiors of the various courts, but no two are precisely alike, and they differ in size and ornamentation, so that the practised eye would soon learn to identify each of them. The judges' bench, the barristers' seats, the strangers' gallery, witness-box, jury-box, &c., are all of oak, and much of the detail is exceedingly effective. The roof is slightly arched (waggon-shaped), and is lighted by a flat semi-opaque skylight. We should imagine that these courts have very good acoustic properties, and that the voice will easily reach all parts without producing any unpleasant echo. We think that the windows in most of them might have been larger with advantage; and it is certain that the pleasantest and most attractive of all the courts is one which has a very large ornamental window facing the judicial bench. The adequate ventilation of the courts has been very carefully considered, and the principle employed closely resembles that in use in the House of Commons. In the

basement at the north end of the central hall is a large cellar in which is a formidable army of steam-boilers and engines. These engines work fans whose function it is to propel air to each of the courts. The points of intake for the air, which are at the bottom of the spaces enclosed by contiguous courts, are carefully guarded from every source of impurity, and arrangements are made by which the air may be either cooled by being passed through a fine spray of cold water, or warmed by traversing a chamber heated by steam coils. The fan drives the air to a space beneath the floor of the court, and beneath every step in the floor (which has necessarily a constantly varying level in order to provide for the numerous raised seats and platforms) is an inlet for the fresh air. The outlet is at the highest point of the wall facing the bench and above the gallery devoted to the public. Through an ornamental grille in this position the foul hot air of the court finds its way into a long corridor, from which rise a series of shafts heated by steam-coils in order to ensure a constant upward stream in the air which passes through them. This machinery for supplying fresh and removing foul air will, as in the House of Commons, be under the care of a special officer, whose duty it will be to regulate the supply according to the demand, and to make the air cool, or warm, dry, or moist, according to the atmospheric conditions which may prevail. The mode of lighting the Courts has not yet been settled. This seems incredible, but we were assured it was a fact. Doubtless the Courts have been erected at a time when the question of lighting, whether by gas or electricity, has been considered in a very unsettled state, but it seems sad to think that the exquisite fittings of the Courts will probably, at no distant date, have to be disarranged in order to allow of the fixing of lights, and the passing of gas pipes or electrical conductors. The ventilation being quite independent of the question of lighting, the choice which may ultimately be made of an illuminating agent will not materially affect the sanitary condition of the Courts; but considering how great is the aid to ventilation afforded by well devised gas-lights, provided with proper flues, and how successfully gas has been used in this way in the Houses of Parliament, we are surprised that in not one of the Courts has such an arrangement been provided for. The gas lights throughout the building are of the crudest, oldest form, flaring extravagantly and fouling the air, but all these fittings are temporary only, and are not to be criticised. Fancy a building of this magnitude being completed in murky London before any comprehensive scheme for its healthy and effectual illumination has been arrived at!

The warming of the corridors and galleries of the building is mainly effected by means of steam coils, furnished with gills. These are placed in all instances against outside walls, and arrangements have been made for allowing fresh air from the outside to pass over the coils. In this way the close feeling which heated coils often give will be avoided.

On the side of the courts furthest removed from the central hall is a building devoted to apartments for persons officially connected with the business of the courts, judges, juries, witnesses (male and female), &c. The private rooms for the judges will, when finished, be very comfortable apartments. The grates in these rooms are modifications of Galton's grates, there being an air-chamber surrounding the fire-box, which communicates on the one hand with the outside air, and on the other with the apartment to be warmed. These grates are none of them smoke-consuming, and anyone who passes the new Law Courts may see volumes of defiling soot issuing from the handsome stone chimneys, which will soon bring Street's magnificent edifice to the grimy level of the rest of the metropolis. One cannot help thinking of Mr. Shaw Lefevre's promise made at the opening ceremony of the Smoke Abatement Exhibition in November last, that in the future our public buildings should be furnished with smoke-consuming grates. Whether it be that the Exhibition failed to furnish a satisfactory pattern, or whether the memories of ministers of State are not very etable, we do not pretend to decide, but certain it is that unless the State shows a determined resolution to diminish the smoke nuisance at all costs, it cannot expect the public to do so, and it can hardly pretend to enforce with any vigour the law which combats this particular form of nuisance. On the occasion alluded to, the First Commissioner of Works said, with regard to the smoke nuisance, that "the whole question was becoming one of very great urgency and importance. That the country would benefit if the greater purity of the air made the cleansing and main-

tenance of the public buildings less expensive was obvious; and it was obvious also that the change would be equally advantageous to the London parks and gardens, and, by consequence, to the health of the inhabitants. It was no easy matter to say what ought to be done, especially as the authors of the mischief were not so much the chimneys of manufactories as the number of private grates, of which as many as 800,000 were lighted in London every morning. He could only hope that for these offenders (*sic*) many of the smokeless grates in the exhibition would be satisfactory and popular substitutes." We recommend this speech to the re-perusal of the right honourable gentleman.

As regards the other sanitary arrangements (*w.c.'s*, urinals, &c.), we may say at once that they are on the whole satisfactory. The bulk of the closets are in the buildings which connect the central hall and the courts. They are tiled throughout with white glazed tiles, and light and air are freely admitted to all of them. The closets are Jennings' plug closets, without traps, and time alone will show whether these will prevent the reflux of sewer air into the building. The soil-pipes are all ventilated by pipes which have only half the diameter of the soil-pipes, and we cannot but think it would have been better to carry the soil-pipe itself to a level with the chimneys, and to have left it open. What is the nature of the connexion of the vertical soil-pipe with the drain, and how the drains of the building are connected with the sewer in the Strand, we were unable to learn. The urinals are of the beaked pattern. The walls of these apartments, we noticed, are finished at the bottom with a wooden plinth. This is clearly a mistake; the plinth should have been of some non-absorbing material, such as slate, and should have been securely cemented to the floor and wall. We were glad to notice in many places that the gas, water, soil, and other pipes were enclosed in a special channel in the wall, made readily accessible by means of a hinged door. Thus the pipes will be able to be repaired without any damage to the building; and what is no less important, the work of that most untrustworthy of creatures, the British plumber, will be constantly open to inspection.

#### ELEVENTH ANNUAL REPORT OF THE LOCAL GOVERNMENT BOARD.

THE eleventh annual report of the Local Government Board gives a summary of the work done in all the numerous departments of that office, and these have so increased in number that it will be impossible to do more than glance at the more important of the matters referred to. The various details of Poor-law administration occupy the greater part of the volume. The amount spent in Poor-law relief during 1881 amounted to £8,102,136, being an increase at the rate of 1.1 per cent. on the amount for 1880; but tested by population and rateable value, there was a slight proportionate decrease. The advantages of giving relief to out-door paupers in "kind" rather than in money are forcibly pointed out. Advances in money are referred to as only a means of obtaining relief, a means, too, which the pauper is under a constant temptation to misapply, whereas relief in kind may be considered as the relief itself, the object of a genuine applicant being, not money, but the immediate means of sustenance. Since 1871 there has been a decrease in the ratio of paupers to population of 23.8 per cent., the principal decrease having taken place in the out-door class of poor, whose destitution is seldom subjected to any satisfactory test. Many workhouses have, indeed, been enlarged with a view of receiving a larger number of inmates in order that the amount of out-door relief administered may be effectually curtailed. The number of insane paupers is steadily on the increase, the total number now reaching 63,524. This is, doubtless, to a large extent due to the increased length of life which, under the present humane system, the pauper-lunatic enjoys, and also to the fact that diseased conditions of brain not formerly recognised as insanity are now included under that designation. In connexion with the subject of the isolation of paupers suffering from infectious diseases, the story of the late epidemic of small-pox is once more told, and it includes an account of the proceedings taken against the use of the Fulham Hospital, together with a reference to the establishment of the hospital

ship *Atlas*, and the tent encampment at Darenth, and some summary of the grounds which led to the appointment of the Royal Commission on Infectious Hospitals. The statistics of child-birth in workhouse infirmaries are dealt with at some length, with special reference to the fact that the death-rate from metria continues to be less in such establishments than amongst the entire population. The point has been often adverted to before, and it is somewhat remarkable, considering the number of deliveries amongst the unmarried who have necessarily, in many cases, been subject to the depressing influences of shame and trouble, to find statistics proving that a pauper woman in a workhouse has as good, if not a better, chance of recovery from childbirth than the ordinary poor woman in her own home.

Dealing next with questions of local government and public health, we find that since the institution of the Board in 1871, loans amounting to upwards of twenty-four millions have been sanctioned for sanitary and allied works to urban and rural sanitary authorities, by far the larger portion—namely, nearly twenty millions—having been advanced to urban authorities. The number of medical officers of health who are appointed subject to the regulations of the Local Government Board, and a moiety of whose salaries is repaid out of the Parliamentary grant, is now 1088. Of this number 543 act for urban, 518 for rural, and 27 for port sanitary districts. In several instances the Board has urged rural sanitary authorities to abandon the practice of appointing poor-law medical officers to act as medical officers of health for their respective districts, when one of the Board's medical inspectors has generally been appointed to inquire into the manner in which the duties of the officers in question have been performed, with the almost invariable result of showing that the sanitary needs of the district could be much more efficiently met by some other appointment. Indeed, it has become clear that an individual must not be invariably regarded as capable of filling an office of one sort merely because he already holds one involving other and very different duties. In most instances where the intervention of the Board has been required in this matter new appointments have been made which have met with the approval of the central authority.

Amongst the authorities who have been alleged to have failed in the performance of their duties, and concerning whom complaint has been made with a view to the exercise by the Board of its compulsory powers, are the Wem rural, and the Ely urban authorities in the matter of water-supply; the Cheshunt, Henley, Newquay, and Acton urban, and the Prestwich rural authorities as regards sewerage. In some of these cases the Board has issued a compulsory order under section 299 of the Public Health Act, but in others either no action has been deemed necessary, or further time has been given to the authorities to reconsider the expediency of voluntarily carrying out the needed works. In connexion with the Sale of Food and Drugs Act, it appears that the number of analyses made during 1881 was slightly in excess of those made in the previous year. One-third of the total was, however, made in the metropolis; in sixty-six boroughs none were made at all; and the number in many other districts was so small as to indicate clearly that there exists a great unwillingness on the part of many authorities, and especially on the part of the Town Councils of the smaller boroughs, to entertain any suspicion that their fellow-townsmen are capable of resorting to adulteration. The difficulties attendant upon obtaining convictions for the sale of milk mixed with water have been very considerably increased by the fact that milk from some ill-fed cows is really inferior in quality to much of the adulterated milk, and that science has, as yet, failed to distinguish between milk to which water has been added and that which, though poor, contains only its natural constituents. The fines inflicted when convictions are obtained are, also, far too small; for, as is pointed out in the report, this class of fraud is far too remunerative when persisted in to be stopped by penalties of ten or twenty shillings.

Dealing next with the question of vaccination, it appears that of the total number of children born about five per cent. remain unaccounted for, and the returns published for 1879 show that the metropolis and York have, and indeed continue to retain, the unenviable notoriety of standing worst in the list. In the metropolis the main default is due to the three districts of Camberwell, Lambeth, and Shoreditch, and some is owing to the circumstances that so many mothers leave workhouses and other lying-in institutions before the statutory period when the vaccination of their children

comes due. This latter cause of default is now being dealt with by many guardians who seek to secure the vaccination of children born in workhouses at as early a period as is found practicable. The supply of calf lymph is now fully maintained, and gratuitous vaccination is in progress twice a week at the Calf Station in Lamb's Conduit-street. This and all the more medical questions will be fully dealt with in the next report of the Board's medical officer, but we may here state that in connexion with the notification of infectious diseases, five more boroughs have obtained powers under special Acts, there being at present twenty-three towns where such notification is in operation. The report next deals with such subjects as the working of the Alkali Act, the circumstances of the London water-supply, the reports made to the Board under the Metropolis Water Act, as also by analysts acting independently of that Act, and the question of local taxation and valuation, and it is followed by numerous appendices, amongst which is a special report by Mr. Gordon Smith, the Board's architect, on certain hospitals in Germany and France, which will repay an attentive perusal.

### GLASGOW POLICE BILL.

A MOST interesting document is the draft of the new Police Bill, which the Glasgow municipality propose submitting for the approval of Parliament at an early date. If it becomes law, the Glasgow public will certainly be under paternal government of the strictest and severest type. Some of the general clauses seem harsh enough, more especially that, which is most criticised in Glasgow, giving powers to ordinary constables to enter houses in a summary and somewhat oppressive way. Even the Lord Provost, an advocate, of course, of the draft Bill, as it stands admits that "the powers are very great that are sought, and might be abused." Under this Bill no one may throw a snowball, fly a kite, make or use a slide, or trundle a hoop within the municipal boundaries; hard times, therefore, seem to be in store for the young people. The clause which provides that "any bull or other dangerous animal" must be "sufficiently secured by means of a rope attached to a ring through the nose of such animal or otherwise" may be commended to the consideration of our anti-vivisectionist friends in quest of a new sensation. The powers asked in regard to dealing with rabid dogs, or dogs suspected of rabies, or which have been bitten by rabid dogs, seem reasonable. In respect to noises, this Bill reads too good to be realisable: No one shall shout or use a bell or other noisy instrument—selling coals, &c.; no one shall use any steam whistle; no one shall play an organ or other instrument of music, or sing opposite or near any building after being requested to desist. If these provisions pass, and if the Glasgow authorities would only set seriously about the purification of their atmosphere, their city might soon become a veritable Arcadia.

But it is the increased powers asked by the Sanitary Authorities which will have most interest for medical men. These powers are pretty much like those which prevail already in many parts of England and Ireland; but they seem ample enough in all conscience. The various sanitary officers are entitled, at all hours of day or night, to enter "any land or heritage within the city which they shall suspect to be not in conformity with the provisions of this Act, under this head." Nuisances are brought very thoroughly under control, whether arising from offensive substances in store, such as rags, bones, blood, guano, paraffin oil, &c.; or from trades or businesses which are injurious to health or which cause annoyance to the neighbourhood, from smoke coming from fires or furnaces, from dirty sinks, soil-pipes, water-closets, &c., or from the keeping of cows or swine.

For the prevention and mitigation of disease, proprietors may be required to cleanse and lime-wash their dwelling-houses, factories, offices, &c.; the present hospitals for infectious diseases, the washing-house for the washing and disinfection of infected clothing, bedding, and so on, and the reception-house, provided as a temporary residence for persons removed from an infected house, are all to be maintained, and if necessary enlarged. Mortuaries and carriages suitable for the conveyance of dead bodies are to be provided. The term "Infectious Disease" is defined as including small-pox, cholera, typhus, enteric fever (otherwise called typhoid,

gastric, and infantile remittent fever), continued fever, scarlet fever, relapsing fever, diphtheria, measles, and whooping-cough, and such other diseases as the Board may from time to time, in the manner prescribed, declare to be infectious. A complete system of notification is also contemplated. As soon as any inmate of any house is discovered to be suffering from infectious disease, the occupier or person in charge of that house shall forthwith give notice thereof to the medical officer. Forms for notification are to be supplied gratuitously to medical practitioners. The medical attendant shall, on becoming aware that his patient is suffering from infectious disease, forthwith fill up, sign, and deliver, or send to the medical officer, a certificate stating the name of the patient, situation of building or ship in which the patient is lying, the name of the occupier of the house or the person in charge, and the nature of the infectious disease. For this the attendant shall receive a fee of 2s. 6d.; but no additional fee is to be paid for any certificate given by him in respect of the same infectious disease, occurring in the same house or ship at the same time, or within thirty days of the first certificate. The penalty for each wilful offence against this part of the Bill is forty shillings. Children who have been suffering from infectious disease are not to be sent to school till they can produce a medical certificate that they are free from disease and infection, and that the house and everything therein exposed to infection has been disinfected; both parents and teachers are responsible for offence against this clause—penalty forty shillings. Infected clothing, bedding, &c., are not to be exposed in common washing-houses or washing-greens till they have been disinfected. When infectious disease occurs in any overcrowded house, or any house which cannot be properly cleansed and disinfected while it is inhabited, all the inmates may be removed to the reception-house and boarded there, without interfering with their lawful business, for a period not exceeding fourteen days. The corpse of anyone dying of infectious disease, when it must otherwise lie in an occupied room, may be removed to a mortuary provided for the purpose. Corpses of those dying of infectious disease may not be transported in any public conveyance, except such a one specially reserved for such uses, unless, or until, the medical officer has certified that every precaution necessary for the public safety has been adopted to his satisfaction. "Wakes" become illegal in the case of those who have died of infectious disease.

To facilitate the tracing of an epidemic to its possible cause, cowkeepers, dairymen, &c. are bound to furnish a list of customers, and to produce invoices and furnish information as to those farmers from whom their milk is obtained. The sale of milk from an infected farm or dairy is prohibited.

When the medical officer thinks that in any existing buildings occupied as sleeping apartments an open space should be provided for the ventilation of such buildings, then this space may be provided, the owner being compensated.

Water used for drinking and cooking is not to be supplied from cisterns exposed in any way to contamination.

Proprietors are required to permit the application of the smoke test by the sanitary inspector, when the latter has reason to suspect that the drains are defective.

Comprehensive powers are also asked for the "regulation" of lodging-houses, more especially as regards licensing, registration, and the providing of medical relief for lodgers in case of illness, &c.

Unwholesome and adulterated foods are then dealt with. All dead meat brought into the city is, before sale, to be taken to certain places, and inspected. Unwholesome meats, &c. (various causes of unwholesomeness enumerated), must not be exposed for sale for food, under a ten pound penalty or sixty days' imprisonment. Butchers' shops and provision shops of all kinds are to be kept "clean and in good condition."

The construction and repair of sewers, the erection, alteration, and use of buildings, and the erection and maintenance of public baths and wash-houses, are all provided for. Adequate precautions are also taken against overcrowding, and for the provision of dungstead, ashpit, and privy accommodation. No apartment is to be used for sleeping in unless it has one or more windows. For persons of eight years and upwards 400 cubic feet of space are allowed in small dwelling-houses used for sleeping in; for children under eight 200 cubic feet. The Board have power to mark on such houses their size and the number who may live therein. It is also declared to be unlawful to let as dwelling-houses any buildings having less than a certain fixed

minimum cubic measurement, varying, in houses of only one apartment, from 700 to 1200 cubic feet; in houses of two apartments from 1200 to 2000 cubic feet; and in houses of three apartments from 1800 to 2400 cubic feet.

Already there is springing up in Glasgow a very decided opposition to many of the provisions of this proposed Bill, many of the public regarding its general clauses as too despotic and tyrannical in their scope and possible application; while in the profession certain of the sanitary measures, whose adoption is proposed, are regarded with extreme disfavour—notably that concerning compulsory notification of infectious disease by the medical attendant. It is felt that not only is it unjust that medical men should be compelled, under a penalty, to report their cases of infectious disease, as if they were in any way responsible for the appearance of such diseases; but it is widely held that such a measure would only lead to more widespread concealment of such affections.

## VITAL STATISTICS.

### HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns, 5681 births and 3477 deaths were registered during the week ending the 28th ult. The annual death-rate in these towns, which had been equal to 21.7 and 20.5 per 1000 in the two preceding weeks, rose again to 21.4 last week. The lowest death-rates in these towns last week were 16.9 in Bristol, 17.4 in Leicester, 17.6 in Salford, and 18.4 in Wolverhampton. The rates in the other towns ranged upwards to 28.3 in Birkenhead, 29.4 in Oldham, 32.9 in Sunderland, and 34.2 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns were 485, showing a further decline from the numbers in recent weeks; 120 resulted from scarlet fever, 103 from "fever" (principally enteric), 95 from diarrhoea, 91 from measles, 54 from whooping-cough, 17 from diphtheria, and 5 from small-pox. No death from any of these diseases was recorded in Wolverhampton, whereas they again caused the highest death-rates in Preston and Sunderland. Scarlet fever showed the largest proportional fatality in Leeds and Cardiff; "fever" in Portsmouth, Leeds, and Birkenhead; measles in Sheffield, Cardiff, and Sunderland; and whooping-cough in Preston and Birkenhead. The 17 deaths from diphtheria in the twenty-eight towns included 9 in London, and 2 both in Liverpool and Sheffield. Small-pox caused 3 deaths in London, and 2 in Newcastle-upon-Tyne. The number of small-pox patients in the metropolitan asylum hospitals, which had been 84 and 78 on the two preceding Saturdays, further declined to 72 at the end of last week; 8 new cases of small-pox were admitted to these hospitals during the week, corresponding with the number in the previous week. The Highgate Small-pox Hospital contained 7 patients on Saturday last, one new case having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 302 and 290 in the two preceding weeks, rose to 355 last week, but were 12 below the corrected weekly average. The causes of 86, or 2.5 per cent., of the deaths in the twenty-eight towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Norwich, Leicester, Nottingham, Derby, Plymouth, and Huddersfield. The proportions of uncertified deaths were largest in Hull, Leeds, Bradford, and Plymouth.

### HEALTH OF SCOTCH TOWNS.

The annual death-rate in the eight Scotch towns, which in the two preceding weeks had been equal to 19.2 and 19.7 per 1000, further rose to 21.4 in the week ending 28th ult.; this rate was identical with those which prevailed last week in the twenty-eight English towns. The deaths referred to the principal zymotic diseases in these Scotch towns, which had steadily declined in the four preceding weeks from 117 to 96, further fell to 89 last week. The deaths from these principal zymotic diseases averaged 3.8 per 1000 in the eight towns, and exceeded by 0.8 the rate from the same diseases in the large English towns. The 26 deaths attributed to diarrhoea were within two of the number in the previous week, and were proportionally thrice as numerous as the deaths from the same cause in the English towns. The 19

deaths from diphtheria showed an increase of three upon those in the previous week, and included 12 in Glasgow, 4 in Dundee, and 2 in Edinburgh. The fatal cases both of scarlet fever and whooping-cough, however, showed a further decline from recent weekly numbers; each of these two diseases caused 8 deaths in Glasgow. The 12 deaths referred to "fever" considerably exceeded the numbers in any of the four preceding weeks; 7 occurred in Glasgow, and 2 both in Leith and Perth. The deaths referred to acute diseases of lungs in the eight towns, which had been 100 and 108 in the two preceding weeks, further rose to 113 last week, and exceeded by 14 the number in the corresponding week of last year. No fewer than 88, or nearly 18 per cent., of the causes of the deaths registered in these Scotch towns last week were not certified.

#### HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 24.4 and 22.5 per 1000 in the two preceding weeks, was again 22.5 in the week ending the 28th ult. During the first four weeks of the current quarter the death-rate in the city averaged 22.3, against 19.8 in London and 17.3 in Edinburgh. The 150 deaths in Dublin last week corresponded with the number in the previous week, and included 5 which were referred to "fever," 5 to diarrhoea, 3 to whooping-cough, and not one either to small-pox, measles, scarlet fever, or diphtheria. Thus the deaths from these principal zymotic diseases, which had steadily declined in the six preceding weeks from 28 to 8, rose again last week to 13; these were equal to an annual rate of 1.9 per 1000, the rate from the same diseases last week being equal to 2.7 in London and 2.0 in Edinburgh. "Fever," to which no death had been attributed in the previous week, caused 5 deaths last week, a higher number than in any week since the first in September. The 5 deaths from diarrhoea, as well as the 3 from whooping-cough, also showed an increase upon recent weekly numbers. The deaths both of infants and of elderly persons showed a decline from those returned in the previous week, while those of children and adults aged between one and sixty years were more numerous.

#### THE SERVICES.

The Queen has approved of the retirement from the Service of Brigade-Surgeon William Henry Colvill, of the Bombay Army, and Surgeon-Major John Davies, of the Bombay Army.

**BREVET.**—Deputy Surgeon-General William Henry Adley, of the Bengal Army, to be Surgeon-General. Surgeon-Major George Edward Whitton, of the Madras Army, to be Brigade-Surgeon.

**ARTILLERY VOLUNTEERS.**—1st Cornwall (Duke of Cornwall's): Surgeon Henry Grenfell is granted the honorary rank of Surgeon-Major. Thomas St. Patrick Tuckey, Gent., M.B., to be Acting Surgeon.

**RIFLE VOLUNTEERS.**—1st Cheshire: Alexander Craigmille, Gent., M.D., to be Acting Surgeon. 1st Inverness-shire (Inverness Highland): James Murray, Gent., M.D., to be Acting Surgeon. 1st Kent: Charles Boyce, Gent., M.B., to be Acting Surgeon. 1st Midlothian (Leith): Acting Surgeon William Alexander Finlay resigns his appointment.

**ADMIRALTY.**—Fleet Surgeon John Breakey, M.D., has been promoted to the rank of Deputy Inspector-General of Hospitals and Fleets in Her Majesty's Fleet, with seniority of October 27th, 1882.

The following appointments have been made:—Deputy Inspector-General Thomas J. Breen, to the Chatham Division of Royal Marines, vice Bremner; Fleet Surgeon Charles Strickland, to the Lord Warden, vice Robertson; Fleet Surgeon Adam B. Messer, Surgeons Charles C. Gedding and William G. K. Barnes, to the Northampton; Staff Surgeon James Bradley, to the Valorous, vice George B. Beale; Fleet Surgeon James N. J. O'Malley, to the Minotaur, vice Cooper; Fleet Surgeon Astley Cooper, to the Agincourt, vice O'Malley; John B. J. O'Meara, to be Surgeon and Agent at Sutton Bridge and Dove-end, vice Haines; Staff Surgeon Alfred G. Delmage, M.D., to the Britannia, vice Trevan; Staff Surgeon Robert Hay, M.D., to the Constance, vice Delmage; Surgeon Samuel C. Browne, to the Indus, vice Popham; Surgeon Charles H. Wheeler, M.D., to the Indus, additional for temporary service; Surgeon Edward

G. Swan, to the Cambridge, vice Peyton; Surgeon Arthur W. E. B. Barrett, to the Duke of Wellington, additional; Surgeon Charles W. Sharples, to the Asia, vice Bradley; Surgeon Robert W. Anderson, to the Lord Warden; Staff Surgeon John Shields to the Tenedos.

### Correspondence.

"Andi alteram partem."

#### "ON ABSORBENT DRESSINGS, ETC."

To the Editor of THE LANCET.

SIR,—In your issue of October 28th Mr. Rogers-Tillstone has ventured some remarks on my paper on Absorbent Dressings, published in your valuable journal of October 21st. I am sorry to be compelled to trespass on your space with a reply, but, as his criticisms are not strictly accurate, must crave the insertion of a few remarks.

In reference to Case 1, red lotion was not used (dry?) to take the place of dry dressing, but as a stimulant and astringent to the granulating surface. Unfortunately, we do not always get union by first intention when antiseptics are not used. The boracic lint was applied dry when I used it, but in the first instance was applied by the house-surgeon. Undue pressure did not cause the ulcer on the surface of the stump, nor did the want of antiseptic dressings cause the erysipelas. The boy was not removed out of the ward on account of erysipelas. He was discharged with a very small portion unhealed; and on the house-surgeon visiting him at his own house he found it was not properly dressed; he was therefore readmitted into the children's ward, but owing to cleaning, &c., going on in the ward, it had to be closed, and the patients removed. A week after his removal to the other ward erysipelas showed itself in the sound leg, and spread afterwards to the stump; this was treated with a solution of iron. We should never have dreamt of applying antiseptics to the sound limb, in which the erysipelas appeared first; perhaps contact with a stump so treated would have prevented it, no matter what amount of infection might have been present.

Case 3, Mr. Rogers-Tillstone says, "recovered in spite of everything, for the sutures ulcerated out and were replaced by strips of plaster." This is not accurate as to the sutures; perhaps one or two did cut their way through; but the acting house-surgeon, who put on the strips of plaster, informs me he removed most of the sutures, and I know that I took some out myself. No doubt the case did get well, and without antiseptic dressings. I rather fancy, if we had no *vis medicatrix nature*, carbolic acid would avail us little. I find, from notes supplied me, that the patient was operated on on May 18th. On the 22nd, four days after, the evening temperature had risen from 101.6° F. on the previous evening, to 103.8° F. The dressings were changed, and next morning the thermometer registered 98.2° F. morning, and 100.2° F. in the evening. About fourteen days after, I amputated through the hip-joint, and at the same time removed the arm four inches below the shoulder-joint, for a railway smash. I applied absorbent wool to the parts, but the man never rallied from the shock, and died a few hours afterwards. I did not know before reading Mr. Rogers-Tillstone's letter that this dry absorbent dressing had anything to do with the unfortunate result, or I should have reported the case with the others. If the man had lived long enough to have a change in the dressing, I should have included the case. The cases reported were to illustrate the advantages of an absorbent dressing, and not to record the number of operations. If carbolic spray would have enabled this man to rally from the shock, then I am certainly culpable.

With reference to Case 4, I sponged out the abscess cavity and the flaps with carbolic lotion, not for its antiseptic properties or with the idea of destroying germs, but for its astringent effects. It was in the operating theatre ready for use, but any astringent solution would have served my purpose. "From his cases we at least learn (?) what we knew before, and see once more that antiseptic dressings were followed by the best results in these cases. The fact that Mr. Berry only publishes his favourable cases takes materially from the value of his communication." Strange logic this; what a man knew before surely he has

no need to learn (?) again. Has Mr. Rogers-Tillstone unlearned anything by reading the paper? I myself have failed to learn "that the antiseptic dressings were followed by the best results." Case 4 had been treated with abundance of carbolic spray and lotion, yet, after his re-amputation and dry dressings, he recovered without a bad symptom.

I do not know of one case that has turned out unfavourably through the plan of dressings adopted, and if Mr. Rogers-Tillstone will kindly give them I shall be as gratified as any of your readers; but a critic who speaks of "antiseptic breath" should at least see that his own words are aseptic. Mr. Rogers-Tillstone was an assistant to one of the staff (who is a general practitioner), and had abundance of time and opportunities, and often visited our infirmary. It is a pity he did not suggest to his principal, or to the house-surgeons who believe in the antiseptic treatment, the mistakes they were committing. I myself would have been willing to sit at the feet of Gamaliel and been taught.

I did not think it requisite to make any reference to the amount of pressure (firm and equable pressure); I expected any tyro would know this, or, if he did not, would consult Mr. Gamgee's little work on the Treatment of Wounds. The pressure must be something more than a loose bandage for the dressings, and something less than sufficient to cause gangrene in the part.

Mr. Rogers-Tillstone's description of the manner in which Listerism is carried out at our institution may be correct. All I can say is that I have seen some of my colleagues operate in an atmosphere of spray, which I have no desire to imitate. If as good results can be obtained by the plan of treatment I adopted in the cases reported, I shall be satisfied to continue, without interfering with the practice pursued by my colleagues.

Apologising for troubling you at this length,

I remain yours truly,

Wigan, Oct. 29th, 1882.

WM. BERRY.

#### "A SIMPLE OPERATION FOR VARICOCELE."

To the Editor of THE LANCET.

SIR,—If Dr. Campbell Black will refer again to my note which you published last week, he will find that, so far from giving a representation of a "granny" knot (a thing I never have employed), there is no knot whatever drawn. The mode of passing the loops above and below the vein is shown, but the knot is of course intended to be made on each loop in the ordinary way, and cut off short. The plan Dr. Black mentions is that advocated by Ricord, and one long adopted by many surgeons, but it is not practicable as a subcutaneous method, which is the chief point in what I wrote about.—I am, Sir, your obedient servant,

W. DUNNETT SPANTON.

Hahley, Staffordshire, Oct. 30th, 1882.

#### SCOTCH DIPLOMAS.

To the Editor of THE LANCET.

SIR,—The readers of THE LANCET must feel indebted to you for the summary of the Minutes of Evidence taken before the Royal Commission on Medical Acts.

As a Licentiate of the Faculty of Physicians and Surgeons, and therefore one of those gentlemen commiserated in your leaders of October 7th and 14th respectively, I beg to say that I feel happy, notwithstanding all the statements and hints thrown out against the Faculty. Many different factors, beyond the titles after one's name, constitute the attainment of professional success.

When I joined the medical classes, in the year 1857, "medical reform" was in the air, and anticipations of increasing strictness in future examinations were in every student's conversation. Since that time statesmen and medical reformers like Lord Palmerston and Professor Syme have passed away, with the cry for medical reform ringing, so to speak, in their ears. The agitation, *mutatis mutandis*, still continues.

Without endorsing the ideas of Herbert Spencer on free competition in medicine, I think that it is over-exacting to expect candidates to answer minute questions in general

education, chemistry, and botany, which thousands already in the profession could not answer, and even the examiners may know only by revision previous to the examinations. What the public require is not a closet philosopher, but a frank, active practitioner, who can speak and write grammatically, frame a good report, and be posted up in the practical details of his profession. It would be of no importance to a swooning puerperal patient that her medical attendant could square the circle, if he were ignorant of the best method to arrest hæmorrhage from the womb. The "well-educated" surgeon, referred to by the late Dr. John Brown in his essay on Nearness of the Nerve, was of no service, when, attending at a duel, he allowed a wounded officer to die, because he could not even temporarily arrest bleeding from the femoral artery.

Some of the witnesses before the Commission admit that the Faculty examinations are thoroughly practical, and yet the witnesses are not happy. If the Faculty pass a supposed incompetent man it is trumpeted everywhere; if the Faculty reject a large number of candidates—Oh! it is because all the candidates are inferior men. Were the insinuations about the licentiates of the Faculty well founded, or the alleged facts numerous, we might expect a proportion of the sick population to be found, in the language of the æsthetic Miss Tuppins, "murdered in their beds" every year. On the contrary, in cases of medical immorality and mal-praxis during the last twenty years, Faculty licentiates are conspicuous by their absence. The working and results of an institution should be the test of its usefulness. It cannot be denied that the licentiates of the Faculty compete successfully in life with the diplomates of other corporations, and that the ordinary meetings of the Faculty of Physicians and Surgeons, its reading-room, and large consulting and lending library, and the examinations of candidates for its licence, tend to the advancement of medical education, and the continuance of men of light and leading in the West of Scotland. By impoverishing the provinces, centralization may have weak points in medical government, as well as in general politics.

You wax warm on the delicate reference to doctors for country districts; but it will surely be conceded that a general practitioner may be fairly educated for all the usual requirements of these districts, and not be a specialist on the eyes, the ears, or the feet. He may be thankful, moreover, for five shilling fees, where his big city brother, a University professor or infirmary teacher, would look askance at any sum less than a guinea. I am, Sir, yours respectfully,

October 27th, 1882.

#### NEWCASTLE-ON-TYNE.

(From our own Correspondent.)

THE study of natural history has always, I might say, presented attractions for northern minds. I need in confirmation of this only mention the names of some of our local students, whose names are known far and wide, to naturalists—viz., the Hancocks, Alders, Bradys, Abbs, Matthey, and others. Owing to the generosity of Sir William and Lady Armstrong the Natural History Society have been enabled to alter the plans for the new museum here, so as to bring it more in accordance with the original designs of the architect. It was intended that there should be a corridor on the east and west sides of the building as it at present stands, but as this would entail an outlay of about £10,000, the Society were obliged to abandon that portion of the plans. It was felt that something should be done to give the exterior of the building a more attractive appearance, but the Society lacked the necessary funds. A short while ago, however, Sir William and Lady Armstrong made the handsome offer of the money necessary to build a corridor seventeen feet wide down the east side, and also a wing on each side of the south end. The corridor will be provided with large ornamental windows, and it will be a very handsome elevation. This extension will, doubtless, improve the appearance of the building considerably, which promises to be an ornament—in an architectural point of view—to the north end of our city. In the wings to be constructed will be cloak, microscopical, and other rooms. The corridor and two wings will mean an expenditure of over

D, a very handsome gift; but when these are added to the main building, the museum, as originally designed, is not complete, for the corridor on the west elevation remains to be added. The Society will be content to wait a while for this corridor. Their chief difficulty at present is the raising of the £2000 yet required to pay for the erection of what may be called the main building, which will cost £32,000. Adding to this the amount that will be required by Sir William and Lady Armstrong, the building, including to present plans, will cost over £38,000. Mr. Cock's own collection of birds quite fill up the largest room. The main building is expected to be opened in the autumn.

Dr. Embleton has kindly sent me a reprint of his address, delivered to the Northumberland and Durham Medical Society, on "Vivisection and Anti-vivisection," in which he cites numerous authorities from all countries, and almost all ages, showing the necessity for properly conducted experiments on animals, and asks "that the present restrictions on vivisection ought at least to be relaxed, so as not to hinder the study of physiology from the country." Of any reading this masterly address of Dr. Embleton and obtaining an anti-vivisectionist, perhaps the best thing to do is, "Pity the poor blind."

The committee of the Ladies' Ambulance Classes, held in the infirmary last winter, after paying all expenses, have voted a surplus in a way at once grateful to the house authorities and useful to the inmates, by presenting two Berlin chairs for the use of the patients.

It is often said that in the course of building improvements and alterations in the streets of large towns, the poor, however they may ultimately benefit, are at first great sufferers. There is a case in point in our own city at the present time, which should excite some attention. The Hospital of the Holy Jesus is an old foundation for the reception of decayed women, or their widows, and will accommodate about forty inmates; they have, besides comfortable quarters in the hospital, coals and other allowances. It was one of the few pleasant places to look at in the ancient part of the town, with its nice bit of grass in front of the quaint building, and the old people toddling about the colonnade, or sitting in the shade and watching the North trains whirl past near, but not so near to be an annoyance. Now all this, or most of this, is changed. Our authorities decided to make a new street, and as yet it is not very clear where it is to lead to, or that it was wanted at all; but at all events they have run the street through the hospital grounds, right in front of the building, cutting up the grass-plot, and obstructing the light and air of these poor people with a hideously ugly iron viaduct. Suppose this new street—contrary to the rule here with some Corporation improvements—fulfils the purpose for which it is intended, these poor old people will be further annoyed with the traffic and other disturbances of a great thoroughfare, instead of the quiet and rest befitting the aged, and evidently intended for them by the founders of this ancient asylum. The corporation is, I believe, the legal guardian of this hospital, and, if it became necessary to obstruct the light and air by this new street construction, it should have removed the hospital, or provided equivalent quarters suitable for the inmates.

The Gateshead Dispensary has, I am glad to see, received a bequest of £500 under the will of the late Alderman Hewitt of that borough. This institution well deserves any support it receives, as it is one of the best managed medical institutions in the North. Some of its house-surgeons have become our most prominent practitioners. This is not to be wondered at, considering the great scope this charity has for its operations. I was speaking to a gentleman the other day who told me that in his early days the population did not exceed 15,000. I believe that at the present time it will not fall much short of 70,000. Some of our merchant princes prefer to have their villa residences in the suburbs of Gateshead, and this is not to be wondered at by anyone who drives along the Durham-road from Gateshead to the Low Fell. The situation is exceedingly beautiful, with the slope of the Team Valley on one side and the wooded hills of Ravensworth, with its embattled castle, on the other, with the Team and Tyne glistening between.

Yesterday was our Hospital Sunday, and as the weather was all that could be expected, or, indeed, desired for the season, we look forward hopefully to an augmented collection.

Newcastle-on-Tyne, Oct. 30th, 1882.

## SCOTTISH NOTES.

(From our own Correspondent.)

THE appointment of Dr. Alex. Ogston to the chair of Surgery in the Aberdeen University was formally announced a few days ago; but as it had been known for some time that the choice had been virtually made, little curiosity regarding the question remained. Judging from past experience concerning Dr. Ogston, the university may be congratulated on the Home Secretary's choice; and it is sincerely to be hoped that his enthusiasm and success as a teacher may rival the genuine fame he has already secured as a scientific and original surgeon. Perhaps the best evidence afforded of Dr. Ogston's fitness for the office is the fact, for which I can vouch, that two distinguished surgeons, who in other circumstances would have been candidates, declined chiefly because they would not compete with Dr. Ogston. Dr. Alex. Ogston is son of the venerable professor of Medical Jurisprudence at Aberdeen, and his brother is assistant-professor of the same subject.

Dr. William McIntosh, F.R.S., was on Saturday last formally installed as Professor of Natural History at St. Andrews. Principal Shairp presided. Professor McIntosh was cordially received by the other professors.

In the introductory lectures to the various courses at the universities several of the professors have this year, and chiefly incidentally, had something to say on the vivisection discussion. It is to the ordinary voter that appeal must finally be made on this as on other questions which are ultimately settled by Parliament, and when the question is calmly discussed with the intelligent citizen there is seldom any but a satisfactory result. The chief danger is that, not the intelligence of the many, but the enthusiastic bigotry of a few active and astute wire-pullers may ultimately decide how science may in future be retarded, and its devotees held up to public scorn. There are many well-educated people who have no accurate acquaintance with the merits of the matter; and without guidance from responsible men, it is not surprising that the floods of anti-vivisection literature, containing statements of the most revolting kind, should bias the judgment of sympathetic natures. Such weighty words as those uttered by Professors Rutherford, Chiene, and Clelland, the former of whom showed the large sacrifice made by the University of Edinburgh, in the interest of truth, in refusing a large sum offered on condition that experiments on living animals should be prohibited, must have a good effect on unbiased minds; while the prominence given to the remarks by the leading Scottish newspapers is a gratifying evidence of good will.

What has been called the Dunecht mystery has been but partially solved by the conviction of one of the perpetrators, and his sentence to five years' penal servitude. No certainty is felt as to the manner of the outrage; but it is believed that more than one person was engaged in the removal of Lord Crawford's body from the family vault. There has been no such case tried in Scotland since the passing of the Anatomy Act.

The Dundee Naturalists' Society, of which Dr. Rorie is the very active President, gave last week a most successful conversazione in the spacious rooms of the Albert Institute. Over a thousand guests were present, and the greatest interest was manifested in the many scientific specimens and novelties exhibited. Mr. P. Geddes, F.R.S.Ed., gave a short discourse on "Some Results of the Study of Biology"; and Colonel Drummond-Hay, a distinguished local ornithologist, lectured on his favourite subject. Altogether the scientific as well as the social success of the meeting must have afforded Dr. Rorie and the useful society over which he presides great satisfaction, and was another proof of the awakening interest in science now so frequently observed on the part of the public generally.

Epidemics of typhoid fever are reported from Kilbirnie and Grangemouth. In the former place about thirty-three cases have occurred, the disease has spread somewhat rapidly, and several deaths have been occasioned. At Grangemouth the outbreak has been traced to a dairy where a case had occurred; several families taking their milk from this source have been attacked; and the whole circumstances have been reported to the Board of Supervision for their advice and that of Dr. Littlejohn. In the meantime an

order has been issued prohibiting the further use of the infected milk till the fever case is removed and thorough disinfection carried out.

## HYPNOTISM IN PARIS.

(From an occasional Correspondent.)

### NO. IV.

THE difference between M. Donato's performances and the experiments of Drs. Charcot and Dumontpallier is this: the subjects for experiment by the latter gentlemen were exclusively female patients more or less hysterical, and those exhibited by M. Donato were almost exclusively young men presumably healthy. This fact, he says, shows the greater magnetic power he possessed over those who experimented on females only; and if he had a subject of the fair sex who accompanied him in all his performances, it was for the sake of convenience, so as to have a subject always at hand. M. Donato's subjects should, according to his own admission, be naturally very sensitive to the magnetic influence, or they should, at any rate, go through some preparation, or rather training, before they could be considered fit subjects. Would this of itself not imply a certain degree of *compérage*? As far as I have seen, the young men are a pale, nervous, delicate-looking set, and are generally shopmen or clerks; and they are always, or nearly always, the same subjects who go through these demonstrations. I have seen them not only go through all the feats described by M. Charcot with his female subjects, but they seemed to be entirely under the influence of his will—so much so, he had only to will certain things and he was implicitly obeyed without even touching his subjects. For instance, he prevented them, while in the magnetic state, from opening their eyes or their mouth, or from speaking in an audible tone, rising when once on their knees, or from giving a blow with the fist while the arm was placed in such an attitude, notwithstanding the strenuous efforts made by the subjects to put these acts into execution. But what is most wonderful is the magnetiser could get them to do certain things which are directly opposed to his verbal injunctions, but are strictly in accordance with his will. Thus, in spite of the repeated orders, which he delivers in the most imperative manner, to open their eyes, their mouth, to pronounce words suggested by their magnetiser, they do just the reverse, and remain silent simply because he wills it inwardly. In some cases, if the subject is magnetised in the midst of a song, he suddenly stops, and resumes it when he is awakened, just at the phrase or the portion of the word where he had left off. Even the special senses are in the power of the magnetiser, which he can alter at pleasure. For instance, one of the subjects magnetised thought he was enjoying an apple while he was eating a raw potato. The mental faculties of the subject are not less under the control of the magnetiser, for he suspends his memory at will, the subject forgets the most common circumstances and the names of articles of every-day life; indeed, he forgets his own name and even the sex he belongs to. Fortunately, this "lapse of memory" lasts only during the magnetic sleep, from which he is roused by a slight whiff in his face. What will partisans of cerebral localisation say to this, and what will pathologists say when they are informed that phenomena such as those described above, which are the result of certain diseased processes of the brain, all of which are of a complex nature and take time to effect their work, are here produced, cured, and reproduced in a few minutes and at the will and pleasure of a "magnetiser?" I ask whether such phenomena can be *bona fide*, even when produced by a man of science? It would seem naive to put such a question, but when I think of the remarks that were made in my hearing at M. Donato's performances, and by men of science, who expressed their belief in the reality of what they had witnessed, and when one takes into consideration the amount of credit obtained for these pseudo-scientific representations through the medium of articles published on the subject in certain periodicals, it seems time that something should be done to expose the fallacy and danger of a doctrine according to which a magnetiser, expert in the art, could command at will the execution of any crime by a subject in the magnetic state. But truth will always prevail, and the impostures,

misconstructions, and misrepresentations are, by the more discerning portion of the public, separated from it as the chaff is from the wheat.

This is what has happened to M. Donato's magnetiser, which were found to be all "chaff," mixed up with a semblance of science, as was shown by a certain number of anti-magnetisers, who had got up opposition meetings. Among others, I may notice one convened by M. Carmelli, Professor of Mathematics at a Government College, who, finding his pupils so full of M. Donato's experiments on animal magnetism, which diverted them from their studies, determined to prove by practical demonstration that the whole affair, whether it be called animal magnetism or hypnotism, was a monstrous humbug. The anti-magnetiser had not much difficulty in doing this: the meeting was announced beforehand, and, of course, the hall was crowded. At the hour appointed M. Carmelli made his appearance in due form, in evening dress and accompanied by a Mademoiselle Mariani, his "agent de démonstration," as M. Donato had his, and who was named Mademoiselle Lucile. M. Carmelli began by assuring his audience that he had never been magnetised in his life, and, consequently, did not possess the mysterious agent called the magnetic fluid. He would, however, undertake to put Mademoiselle Mariani, who also had never been magnetised in her life, through the same processes as M. Donato's subject was in the habit of going through. After a few passes over the forehead and head, a few significant looks, and other manoeuvres usually employed on such occasions, Mademoiselle Mariani fell off into a state of catalepsy. She was then placed on a chair, her body being as rigid as a corpse, with her eyes wide open and fixed from which even the burning of a bundle of phosphorus matches under her nose did not rouse her; there was no quiver in the muscles of the face, and she looked as wise and as lifeless as a marble statue. To show how completely she was under his control the magnetiser roused her by a few passes, and then, by certain other passes, she fell back again into the cataleptic state. A medical man who was present observed that he had seen all this go through at the Salpêtrière except the burning of matches, which would be too vulgar a trick for that institution, and he thought that the subject herself, who looked highly hysterical, might have been a patient in that hospital. While in the cataleptic state her eyes were blindfolded, and she went through the usual tricks as cleverly as any somnambulist by profession. After a short rest and a few fresh passes she again fell off into a sleep. The magnetiser then drove a long pin through the fleshy part of the forearm, but she did not flinch, and not a drop of blood was seen oozing from the wound. She was then placed in the horizontal position between two chairs, her head resting on one and her feet on the other, with nothing to support her back. In this position the magnetiser sat, and even stood upright on her, and she lay as inflexible as a board under the man's weight. This brought down a thunder of applause from the assembly, but it having been intimated to M. Carmelli that it was impossible for any person, not under the influence of magnetism, to go through such a feat as Mademoiselle Mariani had just gone through, he simply reminded his audience that it was a feat commonly performed by clowns at circuses and public fairs who certainly had no pretensions to magnetism, and in order to prove that neither somnambulism nor magnetism had anything to do with it, he proposed rousing his subject from her longest sleep, and that without any passes or blowing on the head, or even touching her. By the simple word of command, "Mademoiselle, levez-vous," she showed signs of gradually coming to by first smiling, and then, stretching out her limbs, she sprang to her feet, and looked none the worse for all she had gone through.

He then explained the trick of passing long needles or pins through the arm without pain, and that it was not necessary to be magnetised to escape suffering, and, suiting the action to the word, he turned up his sleeve and passed a long pin through his own arm. He declared he felt no pain whatever, and invited anyone in the assembly to come forward and try the experiment for himself or herself. No one seemed inclined to attempt it until an old gentleman offered his services, and M. Carmelli put him through the same process as he had just gone through himself, the old gentleman also declaring that he felt no pain whatever. This was the scene of Carmelli's success, and before bringing the séance to a close he wished to impress upon the assembly that there

was no such thing as animal magnetism, that there was certainly an understanding between the magnetiser and magnetised, and that it required some dexterity in performing the tricks and the most scrutinising attention to detect them. As for the feat of thrusting a long needle or pin through the arm, it was a very common one, and the explanation given as to the painlessness and bloodlessness of the operation was that the parts generally selected were those barely supplied with nerves and bloodvessels of any size, as is the case with the upper and fleshy part of the forearm. Besides which, it is a fact well known to surgeons that the muscles are not endowed with great sensibility, and the only pain felt, if at all, would be in the skin, but this would be so slight that, coupled with the dexterity of the operation, the subject would hardly feel any. If the subject be hysterical this would still more favour the success of the feat, as the skin is generally insensitive in this condition; and this would explain how Mademoiselle Lucile bore the operation so well.

This amateur *séance* was most damaging to M. Donato, who was present, and just at the termination he stood up and, in a most frantic rage, denounced his adversary's experiments as unscientific and absurd. Whereupon an altercation took place not only between the principals but between their respective partisans. This, however, was soon put down, and at the breaking up of the meeting many of the audience left with the firm belief that M. Carmelli was a magnetiser *incognito*, or, at any rate, that he and his coadjutor possessed the fluid without being cognisant of the fact, or that they had some motive for not wishing to own it, as they both, Mademoiselle Mariani in particular, acted their part too well to have merely simulated. Be that as it may, M. Donato's glory from that day grew dim, and Mademoiselle Lucile began to find out that she had not been properly treated in the division of the profits accruing from the *séances* and as a natural sequence, she quarrelled with her *pro tempore* lord and master and denounced him as an impostor. Moreover, at an interview a journalist had with her she fully exposed M. Donato's tricks, and made some very interesting disclosures. Among other things she told her interviewer that at times she was rather refractory, and could not fall asleep. M. Donato then resorted to the expedient of dosing her with opium, which made her feel so drowsy and stupid that he used to pinch her to keep her awake till the proper time arrived. But there were times she was so sleepy from an overdose of opium that she could not be roused, and it was then that M. Donato had recourse to the young male subjects already referred to, who were regularly trained to go through the processes told off for them. She further avowed that if she had a choice in the matter she would, by a great way, prefer to have the pins thrust into the arm than be pinched as she was, as the latter operation caused her great pain, and her body was covered with boils in consequence. Nothing has been heard of M. Donato since these disclosures were made, and the rage for exhibitions such as he provided in Paris has consequently declined.

## MEDICAL TRIALS.

### THE BRIGHTON SEWERS BOARD AND THE HOVE COMMISSIONERS.

MR. A. MARTINEAU, the Sussex County Court Judge, sat at the Brighton Town Hall, on the 25th ult., with Mr. James Abernethy, President of the Institute of Civil Engineers, as assessor, in obedience to a mandamus from the Court of Queen's Bench, and under the 73rd Section of the Brighton Intercepting and Outfall Sewers Act, 1870, to hold an inquiry into a dispute between the Sewers Board and the Hove Commissioners. The sewer, the construction of which was begun in 1870, is over seven miles in length, commences on the sea front at Hove-street, Hove, runs along the coast line through Brighton, and discharges itself into the sea at Portobello, about four miles east of Brighton. It intercepts on the line of route and receives the contents of all the sewers in Hove and Brighton, which formerly discharged direct into the sea in front of the two towns at seven different points. The Sewers Board contend that under the Act the two local authorities, the Brighton Town Council and the Hove Commissioners, were bound to convert the old

sewer ends into storm outfalls, to relieve the sewer in time of flood. Brighton converted the whole of the outfall in the Council's jurisdiction, and the Sewers Board now seek to compel Hove to provide outfalls, three of the outfalls in that district having been removed and converted, so that it does not act as an outfall until the water in the ordinary sewers is 5ft. 6in. above the crown of the intercepting sewer. The Hove Commissioners held that the intercepting sewer was constructed for both storm and sewage water, that they were permitted to remove the old sewers by the report of the Board's engineer, Sir John Hawkshaw, and that they cannot be called upon to provide new outfalls. Both Brighton and Hove contribute to the cost and maintenance of the intercepting sewers according to their respective rateable values, and the Commissioners of the latter town contend that if new outfalls are needed in their district they should be constructed at the cost of the common fund.

The hearing of the inquiry was adjourned, and resumed on the 31st ult., when Mr. Cohen addressed the Court on behalf of the Hove Commissioners. He contended that the sewer was constructed for both sewage and storm water, that it was the duty of the Sewers Board, which issued precepts on both the Brighton Town Council and the Hove Commissioners, to construct outfalls if such were found to be necessary, and that the local authority of the Hove district could not, under the Sewers Board Act of 1870, be called upon to carry out the work. Evidence having been taken as to the state of the old sewers at the time of the completion of the intercepting sewers, Mr. Finlay, Q.C., replied on behalf of the Sewers Board, and the Court rose. The Judge will give his decision on the questions of law on November 21st, and in the event of his deciding against the Hove Commissioners, evidence will then be taken as to the work necessary to be carried out.

### IMPORTANT TO MEDICAL OFFICERS.

#### GRUBB v. THE CHESTERTON BOARD OF GUARDIANS.

AT the Cambridge County Court on the 27th ult. the Judge, Mr. Bagshawe, Q.C., gave his judgment in the above case. The plaintiff, Mr. J. S. Grubb, resides at Waterbeach, Cambridgeshire, and is one of the medical officers of the Union, residing at that place. He brought an action against the guardians for the recovery of £3 3s. 6d., being 3s. 6d. for the supply of a truss to a pauper, named Brewer, and £3 for the setting of the leg of a pauper, an old woman named Pearson. As the old woman was a permanent pauper, and the case, in the opinion of the guardians, not an urgent one, the claim was resisted. The leg, it appeared, had been set temporarily by Mr. Bridger, surgeon, Cottenham, and was a case, it was said, for the hospital. His Honour dealt with the larger claim, £3 for treating the woman Pearson for a fractured leg. The pauper held a ticket for permanent relief, and while that ticket was running the woman broke her leg. This was at Cottenham, and the woman was temporarily attended to by Mr. Bridger. On her way in a cart to Landbeach, her home, they met Dr. Grubb. His Honour was satisfied that the woman was not intercepted on her way to the hospital. Dr. Grubb attended the woman and re-set the leg. He sent in his claim for such attendance, but it was suggested that he could not recover, as he did not get a further order as required. The terms of the existing order being without qualification he took to be sufficient. He relied upon Article 76 of the Consolidated Orders, which stated that upon the exhibition of a ticket such person was entitled to receive relief in sickness. He also quoted Article 206, defining the duties of medical officers, amongst which it was stated that upon application made on behalf of the party to whom a ticket was given the medical officer would be bound to supply as if he had received an order from the guardians. In that, there was not a word suggesting that the plaintiff was bound to get any further order. The guardians could not make the woman go to the hospital. It was not the duty of the medical officer to provide extra facilities. Article 177 of the General Consolidated Orders settled the point as to plaintiff's remuneration, namely—£3 for setting the leg. His Honour was at a loss to discover any reason why plaintiff should not be paid and allowed the £3 and costs, the 3s. 6d. being abandoned. Witnesses were allowed.

## MEDICAL NOTES IN PARLIAMENT.

*Treatment of the Sick and Wounded in Egypt.*

On Thursday, 26th ult., Mr. Chaplin gave notice in the House of Commons that on an early day he would "call attention to the condition and treatment of the sick and wounded in Egypt and on the journey home, and the unnecessary sufferings which they have undergone"; and that he would move a resolution.

*Vaccination Questions.*

On Friday, Mr. Hopwood gave notice "To ask the President to the Local Government Board whether he has received further and complete information, through the Foreign Office, from the French Government, on the subject of the infection of fifty-eight soldiers of the 4th Zouave Regiment, to whom it is alleged that syphilis was communicated by vaccination with matter from Arab children."

On Tuesday, in reply to Mr. Taylor, Mr. Dodson stated that he expected the report on the Norwich vaccination inquiry would be printed within a fortnight.

*The Artisans' Dwellings Acts.*

Sir J. McGarel Hogg, in answer to Sir R. Cross, stated on Friday that the Metropolitan Board of Works had given instructions for the preparation of draft schemes under these Acts, with regard to four areas situated in Lambeth, St. George's-in-the-East, Limehouse, and Greenwich respectively. These schemes would come before the Home Secretary for his approval, and if that were obtained they would be submitted to Parliament next session.

*The Army Medical Department in Egypt.*

On Friday, Mr. Childers, in answer to Mr. Fitzpatrick, on behalf of Colonel Milne Home, expressed his regret that Colonel Home, whose gallantry in Egypt was so marked, should have assumed that his medical comrades were guilty of maladministration, instead of asking whether the allegations against some of them would be inquired into. Without admitting the accuracy of the complaints, some of which had been shown to be greatly exaggerated, and others altogether unfounded, he had arranged to defer them to a departmental committee. The Committee was originally appointed in the summer to inquire into the organisation of the Army Hospital Corps, and the reference to it would now be so enlarged as to include all hospital arrangements in the field and on board ship. The right hon. gentleman added that he thought he ought to state, in justice to the medical department, that Sir Garnet Wolseley had greatly praised the medical officers generally in Egypt.

On Monday, in response to an appeal from Mr. Carington, Mr. Childers declined to advise the appointment of a Select Committee or a Royal Commission to deal with this departmental question, for action upon which he was responsible. He was aware of the interests on behalf of which the question was asked, but the committee he had appointed was sufficiently strong to act fairly to all concerned. Surgeon-General Hanbury had not asked for a court of inquiry, but had expressed a wish for the fullest investigation of the complaints made against his officers by certain correspondents. Of course the committee would have the advantage of the evidence of these gentlemen. The right hon. gentleman said he was aware of the pressure which was being used. Strong pressure from different directions had been put upon himself.

On Tuesday, Mr. Gourley asked if there was any foundation for the allegation that the medical service necessary for the proper treatment of the sick and wounded brought home on board Her Majesty's ship *Malabar* was insufficient.—Mr. Childers replied that the committee presided over by Lord Morley would minutely investigate the allegations as to the treatment of the sick and wounded on board the *Malabar* and other ships on which they embarked, and he preferred not to prejudge the committee's report. With regard to the inquiry why what his hon. friend considered an inefficient medical force was sent with the expedition, the whole of that question would come before the committee; but he was bound to say that beyond dispute no military expedition ever left this country with anything like the same proportionate strength of medical officers and attendants. The number of medical officers actually embarked from England, not including India, was 163, besides thirteen who would have left had not the additional drafts been stopped. The numbers of the Army Hospital Corps were eighteen

officers and warrant officers, and 817 non-commissioned officers and men, and in addition twenty-nine nursing sisters were sent by the War Department. Of course, he did not include sisters of mercy or nurses sent by private societies of whom the War Office had no knowledge. After considering the suggestions made to him as to enlarging the committee, he had come to the conclusion that, without in any way qualifying his absolute responsibility in the matter, he might make an addition to the committee. He accordingly asked Sir R. Lloyd Lindsay if he was willing to give the benefit of his assistance. He was happy to say that Sir Robert had consented, and the first meeting of the committee would take place to-morrow (Wednesday).

*Royal Irish Constabulary.*

In answer to Mr. W. Corbet, Mr. Trevelyan said that members of the Royal Irish Constabulary did not pay anything for medical attendance. Complaints were made by the men of the Arklow Division, through the chief inspector, against the medical attendance. Careful inquiry was made by the county inspector, who found the complaints much exaggerated. The removal of the head constable had no connexion with the complaints. Mr. Corbet subsequently gave notice that he will ask the Chief Secretary other questions in reference to the matter.

*Phosphate of Potash.*

Mr. O'Kelly gave notice that he would ask the President of the Board of Trade whether his attention has been called to a pamphlet written by Dr. Robert Galloway of Dublin on the use of phosphate of potash as an antiscorbutic; and if so, whether he will take steps to have its value as a preventive agent properly tested.

*The Murder of Dr. Maclean.*

On Wednesday, Dr. Cameron gave notice that he would ask the Under Secretary of State for Foreign Affairs whether anything definite has yet been done in the way of advancing or securing a settlement of the claim against the Chilean Government for compensation for the murder of Dr. Maclean, the physician to the British Legation, by Chilean soldiery, at Chorillos, in January last.

*Vaccination of Zouaves.*

In answer to the question of Mr. Hopwood, of which notice had been given on Friday (see *supra*), Mr. Dodson said: My answer to the question is that we have not succeeded in obtaining any fresh information upon the subject, and it does not appear that the French Government have any in their possession. With regard to the alleged fact that the disease referred to was communicated by vaccine matter, I am advised that the statement that two children served as vaccinifers for 280 men, and that fifty-eight of these men were operated upon by lymph taken from one single child, is opposed to all experience in vaccination. So far from admitting the fact that this disease was communicated by vaccine matter, I cannot entertain the slightest doubt that such was not the case, more especially as it is expressly mentioned that the children from whom the lymph was said to have been taken were in excellent health.

*The Medical Acts.*

Sir T. Lawrence asked the Vice President of the Council whether it was his intention to introduce a Bill to carry out the recommendations of the Royal Commission on the Medical Acts; and if so, when. Mr. Mundella said the report of the Medical Commission was at present under consideration, but the department had not arrived at such a stage in their deliberations as to enable him to state what course they proposed to pursue.

*The Contagious Diseases Acts in Cairo.*

Mr. Pease asked the Under Secretary of State for Foreign Affairs, whether his attention had been called to the following paragraph in the *Daily News*:—"The first attempt of the Council of Public Health, composed of Europeans and traders, to introduce the Contagious Diseases Act into Cairo is already a great success."—Sir C. Dilke said the Foreign Office had no information whatever upon the subject. They had heard nothing of it, and they were unaware of the existence of a body called the Council of Public Health.

*The War Office Committee.*

Mr. Fort asked the Secretary of State for War whether, seeing that Sir W. Meade holds the office of Director of Transports, Mr. Thomas Crawford that of Director-General

the Army Medical Department, and Mr. George Lawson, of Assistant Director of Supplies and Transports, and thus all officially connected with the Departments which alleged to have failed in properly carrying out their duties during the late war, it would not be more satisfactory if they were as witnesses before, rather than as members of a committee appointed to inquire into matters so intimately connected with their own departments; and whether he is aware that there is a feeling abroad that before a committee is constituted subordinate officers of the Transport and Medical Departments would be unlikely to give the requisite evidence.—Mr. Childers said the main object of the committee was to improve the arrangements of the transport service. No one was more fitted to take part in that work than Dr. Crawford, who had recently returned from India, and the other gentleman named. As to the last part of the question, he could not conceive that any such feeling could exist, inasmuch as the subordinates of the different departments would naturally look to their chiefs to secure them from play when any attacks were made upon them. Mr. H. Smith asked if there were really any charges of failure against either of the departments. Mr. Childers said charges against the transport and medical departments had been made in the newspapers, but he did not attach much importance to them.

## Medical News.

**ROYAL COLLEGE OF PHYSICIANS OF LONDON.**—The following gentlemen were admitted Members of the college on Oct. 26th:—

Benham, Frederick Lucas, M.D. Lond., Notting-hill.  
Edwardes, Edward Joshua, M.B. Lond., York-street.  
Oliver, Thomas, M.D. Glas., Newcastle-on-Tyne.  
Oxley, Alfred Jas. Rice, M.B. Dub., Junior Oxfr. and Camb. Club.

On the same day the following gentlemen were admitted Licentiates of the College:—

Abrath, Gustav Adolph, M.C. Heidelberg, Sunderland.  
Adkins, George, London Hospital.  
Beattie, Henry, jun., Albert square.  
Birch, Henry Priestley, Harley-street.  
Birt, Cecil, Wadale, Sheffield.  
Bollen, Frederick James, South Australia.  
Crick, William Throne, Fentiman-road.  
Dale, Walter Frederick, London Hospital.  
Déqué, Laurent, St. Mary's Hospital.  
Dixon, Henry Charles, Portincale-road.  
Dun, Walter Angus, M.D. Miami, Queen-street, Cheapside.  
Howard, Robert Jared Bliss, M.D. McGill Coll., Guildford-street.  
Hull, Walter, Swallow-place.  
John, David, Swansea.  
Khan, Mohamed Ismail, Montague-place.  
Massey, Henry Massey, Peckham-road.  
Myles, James Percival, St. Mathias Vicarage, Bristol.  
Pantley, John Emanuel, Green-street.  
Penn, John Evans, Cumberland-terrace.  
Powell, John James, jun., Heathlands, Weybridge.  
Robinson, Frederick Gardner, Pendleton, Manchester.  
Sinclair, John, Queen Adelaide's Dispensary, Bethnal-green.  
Skipper, Edward, University College Hospital.  
Stead, Geoffrey, Birmingham.  
Thane, Philip Thornton, Montague-street.  
Tripp, Charles Llewellyn Howard, Royal Free Hospital.  
Williams, Edward Richard, St. Bartholomew's Hospital.  
Wise, Charles Henry, Westminster Hospital.  
Wohnitz, Ferdinand Broër Mathieu, Albert-street.

The following gentlemen passed the Second Examination for the Licence:—

Beatty, Joseph Bensley Higginson.  
Birch, Charles Ormond.  
Croese, Hammond William Rufus Richardson.  
Power, Henry D'Arcy.  
Uppley, John George, Richmond-road.

**ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.**—At the October meeting of the Examiners the following gentlemen passed the Primary Examination for the Double Qualification:—

L. M. Dunlop, M.A., Glasgow. | John Mackie, Aberdeen.

Four candidates were remitted.

The following gentlemen passed the Final Examination, and were admitted Licentiates of both Colleges:—

F. V. Adams, Glasgow. | Sheridan Dean, Glasgow.

Four candidates were remitted.

**FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.**—At the October meeting of the Examiners the

following gentlemen passed the First Professional Examination of the Faculty:—

L. P. Banks, London Hospital.	G. G. Jones, University Coll.
A. C. Boothman, Glasgow School.	J. Mason, Glasgow School.
G. Hunter, Glasgow School.	W. Somerville, Glasgow School.
D. Jamison, Belfast.	A. A. Pulton, Glasgow School.

Ten candidates were remitted.

The following gentlemen passed the Final Examination, and were admitted Licentiates:—

J. H. Blayney, Manchester.	A. M'Anland, Glasgow.
A. Dickson, Glasgow.	A. L. Macphail, Glasgow.
W. Dunlop, Glasgow.	John Mathie, Glasgow.
L. Eminson, Messingham.	A. D. Naismith, M.D., Toronto.
W. Gibb, Glasgow.	N. N. Parakh, Bombay.
G. Hunter, Glasgow.	James Wilson, Glasgow.
E. Kauffmann, Michigan, U.S.	

Twelve candidates were remitted.

**ROYAL UNIVERSITY OF IRELAND.**—The following obtained Honours at the autumn examinations in the Faculty of Medicine:—

M.D. DEGREE EXAMINATION.—First Class Honours: Chas. H. Wise.  
Second Class Honours: J. M'Murray, F. E. Adams.  
M.B. DEGREE EXAMINATION.—Upper Pass Division: John Riordan.  
SECOND EXAMINATION IN MEDICINE (EXHIBITIONS).—First Class, £40:  
Benjamin Hoferd. Second Class, £20: Thomas Grainger, John Kearney, R. B. Gorsuch. First Class Honours: James Chambers, Benjamin Hoferd. Second Class Honours: Thomas Grainger, John Kearney, R. B. Gorsuch, James Norwood.  
FIRST EXAMINATION IN MEDICINE (EXHIBITIONS).—Second Class, £15:  
T. R. Leonard. First Class Honours: J. W. Wilson, T. D. Smyth.  
Second Class Honours: T. R. Leonard, W. B. M'Quitty.

**APOTHECARIES' HALL.**—The following gentlemen passed the examination in the Science and Practice of Medicine, and received certificates to practise, on Oct. 26th:—

Bassett-Smith, Percy William, Alexandra-road.  
Willey, Alex. Gascoigne, Dunbar House, Southsea.

The following gentlemen also on the same day passed the Primary Professional Examination:—

Alfred Kirby, Middlesex Hospital; H. Anderson Sheppard, Charing-cross Hospital; Walter Reginald Tuckett, London Hospital.

**THE LATE DR. YEATES.**—The monumental tombstone provided by public subscription in memory of the late Dr. Yeates, who died at Walthamstow in February last, has been placed over his grave.

**OWENS COLLEGE.**—The Dauntsey Entrance Scholarship, value £100, has been divided between Nathan Charles Haring and Charles Frederick Marshall, who were bracketed equal.

**THE BISHOP of Liverpool** preached the annual sermon in aid of the Derbyshire General Infirmary, at All Saints Church, Derby, on the 26th ult. The Mayor and members of the Town Council attended the service. The collection amounted to £208.

**CAMBRIDGE UNIVERSITY.**—At a congregation held on the 27th ult., Mr. G. E. Wherry, of Downing College, was approved as a University teacher of Practical Surgery. The report, dated October 16th, 1882, of the Council of the Senate, recommending that a sum of £300 be placed at the disposal of the Board of Biological and Geological Studies for the purpose of providing additional teaching for the classes in Morphology during the current academical year, has been confirmed.

**DONCASTER INFIRMARY.**—The report read at the annual meeting of governors and friends of this hospital held last week stated that the number of in-patients was 159, and of out patients, 2348. The annual subscriptions had not decreased, but this branch of income was becoming a source of anxiety. The total receipts for the year were £1721 9s. 8d., being £147 12s. 9d. more than last year. The total ordinary expenditure was £1561 17s. 11d. The balance due to the treasurer was £47 1s. 10d. The Infirmary Sunday collections had yielded £209 5s. 6d., and the Saturday collections £236 7s. 9d., compared with £214 18s. 1d. in 1881.

**DR. E. H. BYRNE, OF DUBLIN.**—The Dublin South City Dispensary Committee, at a meeting held on October 24th, passed the following resolution in reference to this gentleman, who is about to go to Australia:—"That the South City Dispensary Committee, having received the resignation of Dr. E. H. Byrne as medical officer of High-street Dispensary, beg to express their high sense of the manner in which he has discharged his duties, and their high opinion of his professional services, and the great kindness and attention he has given to the poor under his charge; and they wish him every success in future, and much regret the loss of his service."

## Medical Diary for the ensuing Week.

### Monday, Nov. 6.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10½ A.M. each day, and at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M. each day, and at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.; on Tuesday, 9 A.M.

ROYAL INSTITUTION.—5 P.M. General Monthly Meeting.

MEDICAL SOCIETY OF LONDON.—8.30 P.M. General Meeting.—Mr. Edmund Owen, "On Two Cases of Congenital Cystic Hygroma" (living specimen).—Mr. Sampson Gamgee (of Birmingham), "On the Treatment of Wounds and Fractures."

### Tuesday, Nov. 7.

GUY'S HOSPITAL.—Operations, 1½ P.M., and on Friday at the same hour.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2 P.M.

PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. The following specimens will be shown:—Traumatic Hematoma of Vertebral Column; Meningocele Simulating Nasal Polypus; Dissminated Sarcoma; Xanthoma Tuberosum (with microscopical specimens); Pigmentation of the Cervix Uteri; Double Hydrosalpinx; Renal Calculus in a Child; Lung with Impacted Foreign Body; Ulceration of Vermiform Appendix in Typhoid Fever; Sarcoma of Bladder and Prostate.

### Wednesday, Nov. 8.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.

ST. THOMAS'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.

ST. MARY'S HOSPITAL.—Operations, 1½ P.M.

LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

GREAT NORTHERN HOSPITAL.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2½ P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at the same hour.—Skin Department: 1.45 P.M., and on Saturday at 9.15 A.M.

HUNTERIAN SOCIETY.—7.30 P.M. Council Meeting.—8 P.M. Dr. Stephen Mackenzie: 1. "On a Case of Hemianopsia with Hemiplegia;" 2. "On Paroxysmal Hemaglobinuria."—Dr. Coxwell, "On Demonstration of Reflexes in a Case of Hemiplegia."

ROYAL MICROSCOPICAL SOCIETY.—8 P.M. Mr. T. B. Rossiter, "On Observations on Stephanosceres."—Dr. Maddox, "On some Organisms found in the Excrement of the Goat and the Goose."

### Thursday, Nov. 9.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—1½ P.M. Surgical Consultations.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and on Friday at the same hour.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2½ P.M.

### Friday, Nov. 10.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1½ P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 2 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.

CLINICAL SOCIETY OF LONDON.—Mr. Golding Bird, "On a Case of Removal of the Uterus for Fibroid Disease" (specimen shown).—Mr. Clutton, "On a Case of Spina Bifida."—Mr. C. Heath, "On a Case of Separation of the Epiphysis of the Clavicle by Muscular Action."—Dr. Goodhart, "On Six Cases of Diptheria treated by the Local Application of Borax or Boracic Acid."—Mr. Golding Bird will exhibit a Case of Transpatellar Excision of the Knee.

### Saturday, Nov. 11.

KING'S COLLEGE HOSPITAL.—Operations, 1 P.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

## TO SUBSCRIBERS.

IN order that no encroachment may be made on the usual contents of our number by the publication this week of Dr. Richardson's elaborate Report on the Sanitary Condition of Brighton, we have increased the size of our current issue to the extent of sixty-four columns. THE LANCET of the present week therefore consists of 112 pages.

## Notes, Short Comments, and Answers to Correspondents.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*All communications relating to the editorial business of the journal must be addressed "To the Editor."*

*Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.*

*Lectures, original articles, and reports should be written on one side only of the paper.*

*We cannot prescribe, or recommend practitioners.*

*Local papers containing reports or news-paragraphs should be marked.*

*Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."*

## "TETANUS FOLLOWING VACCINATION."

DR. H. J. BERKELEY records in the *Maryland Medical Journal* a case headed as above. The patient was a man aged forty, tall, and healthy-looking. Some days after the operation, which was performed about the middle of January last, he exposed himself to severe cold, and the arm became much swollen, and the integument around the scar inflamed. No other lesion could be detected anywhere in the body. On February 7th he noticed a little stiffness of the jaw, and there was slight opisthotonos, accompanied on the following day with profuse perspirations and muscular spasms of the lower extremities. These symptoms increased in severity till the 18th, on the evening of which day death took place, the pulse at noon having been 120, the respiration 44, and the temperature 102°. The treatment throughout was by chloral hydrate and kalium bromide. Constipation was persistent during the entire illness, and was occasionally relieved by an enema. Dr. Berkeley acquits the virus of any share in the fatal result in this case, the "lesions of the peripheral nerves involved in the inflamed tissue probably being the immediate factor."

Dr. Tarleton, G. P., and others.—We strongly disapprove of the circulation of the post-cards referred to.

## "THE DANGERS ATTENDING SHAMPOOING."

To the Editor of THE LANCET.

SIR,—The article in your journal of Saturday last has, I am happy to say, created much comment upon a very important subject. As, however, the inquiries here are both frequent and searching, it has occurred to me that the uninitiated, and especially our foreign patrons, may construe the matter to the disadvantage of this company.

I hope, therefore, you will allow me to state that you correctly describe our arrangements when you say "in one of the most celebrated West-end houses we noted that the pipes from the basins all led on to the roof of an out-house, and there the soapuds and water travelled some four or five yards in the open air before entering the waterspout. A back current could, therefore, only bring in air from the roof, that is, air as pure as any to be had in London."

I may add that the system of water-supply and waste at this establishment is under weekly supervision.

I remain, Sir, your obedient servant,  
Old Bond-street, London, Nov. 1st, 1882.

H. P. TRUEFIT.

\* We have likewise received a communication from Mr. Robert Douglas, of Bond-street, in which he asks us to state that every basin in the gentlemen's room in his establishment delivers into an open courtyard and into the open air; one waste pipe above a trap, and another under what is called a ventilated trap. Thus no sewer-gas or air from the drains can pass up the main waste-pipe and along the tributary pipes leading to the several basins. There is even a more thorough disconnection in the case of the waste from the ladies' basins, for there the main waste-pipe delivers into a large hopper, close to the exterior of the window.—ED. L.

## A LEESMAGHAW GEOLOGIST.

THE death, about three weeks ago, of Mr. Robert Slimon, surgeon, Leesmaghew, has removed one of those self-educated, enthusiastic men of science, who seem in a manner indigenous to Scotland. Mr. Slimon began his working life as a hand-loom weaver in Douglas. From Douglas he removed to Cumnock, where he entered on the trade of a fancy box maker. After spending some time in Cumnock he went to Glasgow, and obtained a situation in a druggist's shop. While serving as a druggist, Mr. Slimon entered the medical classes in the University, and obtained the licence of the Faculty of Physicians and Surgeons. He then left Glasgow for Leesmaghew, where he settled down, and spent a long, busy, and respected life. From his earliest days Mr. Slimon was a close observer of nature. While yet little more than a boy he became interested in the study of geology, and this study he was enabled, after his migration to Leesmaghew, to pursue with much success. His researches, indeed, into the upper silurian system were rewarded by the discovery of the crustaceans in the rocks of this system, a discovery which has made his name celebrated in the annals of geology. His collection of these crustaceans was altogether unique. Sir Roderick Marchison, who was a frequent correspondent of Mr. Slimon's, inspected it with great care and interest, and made special mention of it at the '54 meeting of the British Association in Glasgow. In addition to his silurian crustaceans, Mr. Slimon possessed an extensive palaeontological collection of the flora and fauna of the carboniferous rocks of the parish of Leesmaghew, and this collection he utilised, in some measure, in his "Geological Account of Leesmaghew," a monograph which, while limited as to its scope, is a model of minute and exact research. Mr. Slimon was, many years ago, elected a corresponding member of the Geological Society of London, a distinction in regard to which he manifested a very pardonable measure of gratification, and even pride. At his death, Mr. Slimon had attained the mature age of seventy-four years.

Mr. Chavasse.—Thanks. The reports will be acceptable.

F. A. M.—A month's notice.

## ON THE INTERNAL ADMINISTRATION OF OHRYSOPHANIC ACID IN PSORIASIS.

To the Editor of THE LANCET.

SIR,—Since the publication of Dr. Napier's interesting article on the above subject, which appeared in your columns of May 20th, I have given this drug an extensive trial, and have been remarkably struck with the result.

In the first case in which I tried it the action proved so rapid and effective that I think it worthy of record in connexion with the other cases that have been brought forward. A young, delicate lad, fourteen years of age, came to me with well-marked psoriasis of five years' standing. The abdomen and chest were covered with numerous rings about the size of a florin. The upper and lower extremities were also affected; the patches were here, however, much smaller and less numerous. I ordered him one-fifth of a grain of the acid three times a day in sugar of milk, with directions to take the powders about half an hour after meals. No external application of any kind was given. I saw him the following week. Some of the patches were beginning to fade, whilst a few had actually disappeared. The following week those on the chest had entirely died away; the others were fading quickly, especially those on the belly. At the end of the third week he was practically cured, only a few small spots remaining on the arms and legs. He continued the medicine (one-tenth of a grain) for a month afterwards, and, as I have not seen him since, I conclude there has been no return. The dose (one-fifth of a grain) was not increased throughout. The boy never complained of any nausea or sickness, or any other ill-effects from the use of the drug, so common when larger doses are given.

I have tried it in several other cases with marked benefit, but not with such success as in the case mentioned. I have generally begun with one-fifth of a grain, and have rarely exceeded that amount, having found that where the smaller dose failed to do good a larger dose was equally ineffectual. I have also noted the fact that the disease is more amenable to treatment when occurring in strumous cachectic patients than in those of a stronger and healthier constitution.

I am, Sir, yours, &c.,

F. W. CLETON, M.R.C.S. Eng.

Easy-row, Birmingham, Oct. 31st, 1882.

Dr. D. W. Corfield.—The list was published in our last issue.

Mr. Gordon Holmes.—Yes.

## "PERFORATING ULCER OF FOOT AND LOCOMOTOR ATAXY"

To the Editor of THE LANCET.

SIR,—Out of three well-marked cases of locomotor ataxy which I have had considerable opportunities of observing, one had an intractable abscess situated over the outer tarsometatarsal joints of the left foot on the dorsum. This was open for the last two years of the man's life. It certainly could not come under the title of perforating ulcer, but I always connected it with the nerve affection in my own mind.

I am, Sir, yours, &c.,

E. E.

October 30th, 1882.

## HOSPITALISM AND PUERPERAL SEPTICEMIA.

A CORRESPONDENT says that, having practised for some years near a provincial hospital, he has been continually struck with the fact that all people dying during or soon after their confinements have been attended by some one of the surgeons on the staff of the hospital. It is undoubtedly true that hospital surgeons, especially those practising midwifery, need to take special precautions in the way of cleanliness and antisepticism. But is it not hospital surgeons to whom we are mainly indebted for the science of antisepticism and the practice of it? We think there is something partial in the observation of our correspondent; but hospital surgeons who are also obstetric practitioners will not blame us for directing attention to the point raised, and for advising rigid care, cleanliness, and antisepticism.

*James Ross, M.D.*—It is most unreasonable to be required to give receipts without at the same time being paid. There can be no justification of such a system. The facts given prove its unsoundness, and should be forwarded to the higher authorities if the fees are not quickly forthcoming.

*Mr. W. A. Gilligan.*—Dunglison's (Churchill).

## "THE USE OF THE FORCEPS IN MIDWIFERY."

To the Editor of THE LANCET.

SIR,—In reference to the letter of your correspondent, Mr. E. A. Rugg, permit me to make a few remarks in regard to the manner in which that gentleman draws his conclusions as to the necessity of using forceps in labour, and from which, as a standpoint, he would seek to criticise others.

Mr. Rugg asserts that he has used forceps in 12 cases out of "of the last 400" attended by him, and that "half of these cases might have terminated without the use of forceps." He also states that he is "not at all addicted to the use of instruments where they can possibly be avoided." This seems like a contradiction, as stating no condition of labour indicating the use of forceps, he thus acknowledges himself, judged from his own standpoint, "addicted" to "meddlesome midwifery."

In regard to Mr. Rugg's "rule of practice not to wait more than three hours when there is no advance in the second stage of labour," it seems to be a rule more suited to his convenience than that of the patient; and if Mr. Rugg adheres to this rule in his next 400 cases he attends he will use forceps many times when it is neither "necessary nor desirable" so to do. Mr. Rugg ought to know that this is a very unsafe guide in determining how long labour should remain unaided in the second stage, and that many labours prolonged in the second stage may terminate satisfactorily without interference. On the other hand, it would in some cases be injudicious for one experienced in obstetrics and in the use of the forceps to allow the patient to exhaust herself for anything like three hours before delivery.

It is not, however, my intention to discuss the indication for, or the benefits which arise from, the timely use of forceps in the hands of a skillful person, but merely to hint at some of the sources of fallacy which may have prejudiced the use of instruments in Mr. Rugg's estimation, and which his confessedly small experience of them has failed to remove.

I would refer Mr. Rugg to the works of modern writers on the subject of the forceps, the perusal of which, I feel sure, would void his mind of the ancient prejudice, and satisfy him that the most potent arguments of the opponents are founded upon imperfect and limited experience, or cases in which, through delay in its application, the mischief had in all probability already taken place.

As Mr. Rugg takes exception to the forceps proportion of the master of the Rotunda, I would remind him that one is scarcely justified in estimating the necessity for forceps in such an institution by comparison with the statistics of his own cases in private practice, the circumstances being so widely different, as they are even in comparing one practice with another.—I am, Sir, yours truly,

Britannia-terrace, Kensal-road, W.

ISAAC WILLIAMS.

Oct. 23rd, 1882.

*Psychologist.*—There were four generations of Monroes. There is a portrait of Dr. Edward Thomas Monro in the dining-room of the Royal College of Physicians; it was painted by his son, Dr. Henry Monro.

## "TESTIS IN PERINEO."

To the Editor of THE LANCET.

SIR,—I venture to ask for space to record another instance of the above in a child one month old, brought to the out-patient department of this hospital, and seen by Mr. Sansome (an. surgeon) and myself. The mother brought it as "ruptured." The right half of the scrotum seemed longer than the left, was flaccid, and contained no testis. This was felt in the perineum, a little below the junction of the scrotum. It was noticed some days after birth. Mr. Sansome proposed a similar procedure to that suggested in THE LANCET of October 21st—viz., the subcutaneous division of the separating membranes; but the child, like its testis, has wandered, and sought some other course.

I am, Sir, yours truly,

F. F. GRAMAN, House-Surgeon.

The District Hospital, West Bromwich,  
Oct. 27th, 1882.

## PITYRIASIS NIGRA.

DR. PRATT thinks that, after all, the case to which he referred in a note under the heading "A Query" may be one of pityriasis nigra, and directs attention to an instance somewhat similar which occurred in the practice of Mr. Teevan, and was brought under the notice of the Royal Medical and Chirurgical Society in 1845, the report of which appears in THE LANCET of July 10th of that year.

A Collector.—There is a portrait of Dr. Thomas Fuller prefixed to his Pharmacopœia Domestica. He wrote the following lines on a left-handed writing master:—

"Though Nature thee of thy right hand bereft,  
Right well thou writest with the hand that's left."

Mr. Cauty's paper is marked for insertion.

## UNQUALIFIED PRACTICE BY MEDICAL STUDENTS IN GLASGOW.

To the Editor of THE LANCET.

SIR,—In the interest of the community, as well as the medical profession, I should like to draw your attention to a few facts in reference to a system carried on here. Some time ago the trustees of Anderson's College thought that they would increase the popularity of their medical school if they were to give outside practice to their students. With this no one could find fault if confined within certain limits, but it has become otherwise, and has become a serious hurt to the people, as well as to the general medical practitioner. It seems anyone leaving name and address at their dispensary may have out-door attendance. Hundreds who are quite able to pay both for attendance and medicine take advantage of this. This of itself is not the worst feature of the practice, but that young men just commencing to study (youths who have not passed their first professional examination) should be sent out to visit and to undertake the treatment of the most delicate and serious ailments, is not altogether free from danger, and confers a doubtful benefit upon the unfortunate sufferers. The most grievous part of this practice, however, is that some of these young men open up drug shops and visit for the dispensary, and in the district in which they illegally set up their shop induce people to go there for medicine as well as for advice, and, under the pretence of doing work for the dispensary, advertise themselves (verbally) as doctors, and thus obtain profit for their labour. Is this not allowing quackery in its very worst form, as the people are under the belief that they are having the gratuitous advice and attendance of bona fide medical men?—I am, Sir, yours respectfully,

October 23rd, 1882.

GLASGOW.

*Surgeon.*—The election of Fellows into the Council of the College of Surgeons is vested entirely in the Fellows. Members have no share in it. There are, according to the last published Calendar of the College, 1184 Fellows and 16,003 Members of the College, making a total of 17,279 Fellows and Members.

*Mr. F. W. Strugnell* will find the correction made on page 734 in our last issue.

## CASE SIMULATING HARE-LIP.

To the Editor of THE LANCET.

SIR,—The following case may be deemed of sufficient interest for insertion in your pages.

Being called to see C. H.—, ten months old, on August 5th, about 12.30 P.M., I found a severe cut on the upper lip, extending through the septum of the nose right through the lip. This accident occurred as follows:—The foot of an iron bedstead went through the flooring of the bedroom and upset some ornaments that were on the mantelpiece close by. On examination I found that the wound was quite through, and sloping rather to the left side, and that she could take the breast very well. The wound was put together by means of two silver sutures, and adhesive plaster was applied to give it a better support. One suture, nearest to the nose, was removed on the tenth day; the other was left till the fifteenth day, when it was removed, and has left hardly a mark to be seen.

The points of interest in this case are—(1) there was very little hemorrhage, (2) the child could suck all along, and (3) the rapid recovery.

I am, Sir, yours, &c.,

W. E. WILLIAMS.

Daylan, Oct. 1882.

M.R.C.S.—Such shabbiness we should hope is not common. There may, however, be some reason for it, which time will explain.

D. H. R.—No card enclosed.

## "INUNCTION IN SCARLATINA."

To the Editor of THE LANCET.

SIR,—"Cutis" asks for information regarding this very valuable mode of treatment by inunction in scarlatina. Since Dr. Taylor's paper, in THE LANCET of 1849, many have used inunction with marked satisfaction to themselves and patients, and, so far as I ever heard, with no injury to the kidneys of the latter. If "Cutis" refers to me he will find the information he seeks regarding hamamells.

I am, Sir, yours, &c.,

MEDICAL DIGEST (Section 80: 4 & 361.1).

Boundary-road, N., Oct. 30th, 1882.

## THE POSTAL MICROSCOPICAL SOCIETY.

WE understand this society is still in existence. The secretary is Alfred Allen, Esq., Bath.

**Bibliopole.**—The surgical writings of John of Ardena are scarce and valuable. There is one in manuscript in the British Museum; there was also one in the library of Dr. Mead, and there is one which belonged to Queen Mary, afterwards in the library of Mr. Towers, of Essex. When Mr. South was President of the College of Surgeons he had one translated for the library, where it may be seen on applying to Mr. Chatto, the librarian.

**T. M.**—The studentships in Human and Comparative Anatomy have long since been abolished at the College of Surgeons, no election having taken place since 1855.

## "HAMAMELIS VIRGINICA."

To the Editor of THE LANCET.

SIR,—I cannot give your correspondent, "C.," any information regarding the tincture of hamamelis, not having used it; but I can speak most highly of hazeline, the active principle of the witch hazel. I have prescribed hazeline as an injection (twice daily) in several cases of hemorrhoids with most satisfactory results, relieving cases that had resisted all other treatment. It does not cause pain; on the contrary, relieves all unpleasant symptoms.

Hazeline was highly recommended two years ago for cases of hæmorrhoids, epistaxis, melæna, &c.; but administered internally it has disappointed me in such cases. As a local application I have never known it fail, and I consider it invaluable as such in the treatment of indolent and varicose ulcers, &c. Injected into the nostrils in that common complaint, "cold in the head," it gives immediate relief.

While the correspondence on the "abortive treatment of gonorrhœa" was being carried on in THE LANCET I had opportunity of using hazeline as an injection in a case of "old gleet," and was agreeably surprised to find that, after a few injections, my patient was cured. I also had the opportunity of using it in the early stage of gonorrhœa, and with good result; and I believe that if any of your readers who may have more opportunity should give the drug a fair trial they will not be disappointed with the "abortive treatment of hazeline" when using hazeline as an injection. A glass syringe should be used; metals decompose hazeline. I am, Sir, yours truly,

Chesterfield, Oct. 30th, 1882.

W. S. SYMES.

**A Provincial F.R.C.S.**—The number of Fellows of the Royal College of Surgeons whose addresses are known, residing in London and within a radius of ten miles from the General Post-office, is about 440. Upwards of eighty Fellows appear in the College Calendar with no address to their names.

**Theta.**—In the absence of any expressed wish of the patient to the contrary, the case should be handed over to the ordinary medical adviser.

## REMOVAL OF HAIR FROM THE FACE.

To the Editor of THE LANCET.

SIR,—Can you or any of your readers help me under the following circumstances? One of my patients has a large tuft of thick hair occupying a prominent position upon the face, and which it is very desirable to get rid of permanently. Depilatories have been had recourse to without affording any satisfaction, and latterly epilation has been tried, with no better result. The individual hairs are extracted easily enough, but as their bulbs cannot be induced to accompany them, a fresh capillary crop takes the place of the one just reaped.

Any treatment that has acted well in a similar case, or one that theoretically holds out a prospect of doing so, will be heartily welcomed by

A PUZZLED PRACTITIONER.

October 24th, 1882.

## SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year ..... £1 12 6 | Six Months ..... £0 16 8

TO CHINA AND INDIA ..... One Year, 1 16 10

TO THE COLONIES AND UNITED STATES .. Ditto, 1 14 8

Post Office Orders should be addressed to JOHN CROFT, THE LANCET Office, 423, Strand, London, and made payable at the Post Office, Charing-cross.

Notices of Births, Marriages, and Deaths are charged five shillings.

Cheques to be crossed "London and Westminster Bank."

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on page 2, which not only affords a ready means of finding any notice, but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance. Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET. Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed. Advertisements are now received at all Messrs. W. H. Smith and Sons' Railway Bookstalls throughout the United Kingdom, and all other Advertising Agents.

Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher.

Agent for the Advertising Department in France—J. ASTIER, 67, Rue Caumartin, Paris.

## HYSTERIA.

To the Editor of THE LANCET.

SIR,—Can you or any correspondent kindly inform me of any charitable institution where the "Weir Mitchell" treatment of hysteria is carried out? A small payment might perhaps be arranged for.—Yours truly,  
October 30th, 1882.

E. W. JOLLYE.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Sir William MacCormac, London; Mr. Lawson Tait, Birmingham; Mr. Roger Williams, London; Mr. Collyer; Dr. Hughes Bennett, London; Dr. J. A. Campbell, Garlands; Mrs. Gothard; Messrs. Nichols and Co., London; Mr. Chavasse, Birmingham; Mr. Harris, Norwood; Mr. German, West Bromwich; Dr. Pratt, Appleford; Mr. Laurent, Bedford; Dr. Collier, London; Mr. Reese, London; Mr. B. Shillitee, London; Mr. Briscoe, London; Mr. M'Mann, London; Mr. Berry, Wigan; Mr. Christopher Heath, London; Mr. Crombie, Brighton; Mr. Rochfort, Chesterfield; Mr. Williams, Portsmouth; Dr. Sinclair Thomson; Mr. Savory, London; Dr. Caddy, London; Mr. Barrand, London; Mr. W. E. Lloyd, Bristol; Dr. Hudson, Leeds; Mr. Beacom, Esker; Dr. Eastwood, Darlington; Messrs. Waugh and Co., London; Mr. Bennett, Liverpool; Messrs. Ure and Co., Toronto; Mr. Hall, Blackpool; Mr. L. Bullock, London; Mr. Brown, Westgate-on-Sea; Mr. Bullivant, Derby; Dr. Creery, Dinapore; Dr. Corfield, London; Mr. Shaw, Ayr; Mr. Clarke, Aberfeldy; Mr. Woodcock, Bradford; Dr. Schmitz, Neuenahr; Mr. Clifton, Birmingham; Dr. S. G. Barnes, Eyr; Dr. Corfield, London; Mr. Symes, Chesterfield; Mr. Cameron, Stroud; Mr. R. Douglas; Mr. Harding, Leeds; Mr. Jalland, York; Dr. Maxwell; Dr. Leonard Sedgwick; Mr. Reginald Harrison, Liverpool; Dr. Hutton, Hartshill; Dr. Eshelby, Frocester-court; Mr. Bain, Dundee; Mr. Hosker, Bournemouth; Mr. Turlington; Mr. Roberts, London; Mr. Shuttleworth, San Remo; Mr. Truman, Nottingham; Mr. Nutra, London; Asinus; Fornix; M.D.; Septicæmia; M.R.C.S.; M.D., Carlisle; Medicus B.; M., Urbridge; P. D., Oldham; W.; &c. &c.

LETTERS, each with enclosure, are also acknowledged from—Mr. Lake, Plymouth; Mr. Kirkpatrick, Woodbridge; Mr. Quinton, Norwich; Mr. Hay, St. Helens; Mr. Crompton, Bury; Messrs. Beal and Co., Brighton; Mr. Eariam, Abbott Bromley; Mr. Eschwaga, London; Mr. Noakes, Exeter; Mr. Hyatt, Shepton Mallet; Mr. Young, Bray; Mr. Whitford, London; Mr. Coates, Southsea; Mr. Hetherington, Ipswich; Mr. M'Dougal, Dorsey; Dr. Roberts, Sheffield; Mr. Hicks, Hendon; Messrs. Bell and Co.; Mr. Cottle, Preston; Mrs. Carter, Bristol; Dr. Coombs, Castle Cary; Mr. Darke, London; Mr. White, Bayswater; Mr. Millican, Warwick; Mr. Frampton, Weston-super-Mare; Mr. Phillips, Seale; Mr. Lake, Gravesend; Mr. White, Bayswater; Dr. Dobell, London; Mr. Sarkle; Mr. Simpson, Dungannon; Mr. Garrod, Mexborough; Mr. Harrison, Sherburn; Mr. Heyworth, Rawtenshaw; Messrs. Keith and Co., Edinburgh; Dr. Low, Norwich; Mr. Woodland, London; Miss Armitage, Nottingham; Mr. Roberts, Alfreton; T. K.; E. J., Tring; F. B. F., Dunstable; H. H.; G. V. D.; Medicus, Dublin; H. B., Nottingham; Lancet, Chesterfield; J. H. R., Whitehaven; Physician, Holborn; Beta, Manchester; S., Arlo; T., Oldham; J. G.; J. M. J.; Tenax, Liverpool; D., Blackwater; A. B., Walton; Miss H., Southport; Dispenser, London; C. B. A.; Lex, Manchester; Superintendent, Seaford; Surgeon, Bury St. Edmunds; Mentone, London; A. B., South Bank; S. W.; Medicus, Bowles; &c. &c.

ABSTRACT OF A

Clinical Lecture

ON

HEMORRHAGE INTO THE CAVITY OF THE ARACHNOID:

ITS SURGICAL AND MEDICO-LEGAL ASPECTS.

*Delivered at the Middlesex Hospital on Jan. 17th, 1882,*

By HENRY MORRIS, M.A., F.R.C.S.,

SURGEON TO, AND LECTURER ON SURGERY AT, THE HOSPITAL.

THE subject of hæmorrhage into the inter-arachnoid space has been one of the battle-fields of pathologists. The source of the blood is generally difficult to trace. It has been thought at one time to proceed from one of the vessels of the dura mater, at another from the pia mater; or, again, from one of the small veins which cross between the brain and the large venous sinuses of the dura mater. Probably it rarely comes from a vessel of the dura mater, because blood from such a source, whether the skull be fractured or not, is far more likely to separate the dura mater from the bone and escape into the space between. When the brain is lacerated and the visceral arachnoid torn, the blood found in the inter-arachnoid space is pretty sure to have come from the pia mater. Such cases are comparatively common. But if there be no fracture of the skull, no injury to the dura mater, no tear in the visceral arachnoid, and no bruising or laceration of the brain, it is impossible to say whence the effused blood is derived.

Then as to the state of the effused blood. It may be liquid or solid. If solid, it may be coagulated in clots, or in a thin membranous layer covering more or less of the convexity of the cerebrum. If in the form of a membrane, it may become a bond of union between the visceral and parietal arachnoid; or it may be adherent to the arachnoid covering the dura mater, but free on its under surface; or it may be quite non-adherent on both its aspects. In either the fluid or the solid state, if it retain all or nearly all the natural colour of the blood, and if it have none of the characters of false membrane or of a cyst, there is no room to doubt as to its nature. But when in the inter-arachnoid space there have been found layers looking like false membrane with more or less altered blood in them; or when these layers have consisted of yellowish fibrine only, with or without effusions of recent blood, in the form of small cysts, between them; or, again, when, as in some extravasations of old date, the mass has assumed the appearance of a single complete cyst containing blood, and has perhaps fallen out entire from its position,—much questioning has arisen. In all such cases, the question has been whether the cyst-like membrane has been formed from the extravasated blood itself; whether the blood causes the false membrane by inflammation, and thus an exudation of lymph surrounds the extravasation; or whether a vascular false membrane yields the blood by bleeding.<sup>1</sup>

The blood may become so firmly attached to the arachnoid surface of the dura mater as to appear like a thickening of that membrane. Or it may be so closely fixed to it by a smooth and glistening serous-like covering as to look as if the blood were effused between the dura mater and the parietal arachnoid; but such can be proved not to be the case by peeling off this false membrane, and thus exposing the parietal arachnoid, roughened and discoloured it may be, but still adherent to the dura mater.

Ample evidence has been produced by the French pathologists, and by Sir George Burrows, Mr. Prescott Hewett, and Dr. Wilks in this country, that all these various appearances result from extravasation of blood between the layers of the arachnoid.

But besides their great interest to the pathologist, these interarachnoid effusions are of much importance to the practical surgeon. They have been met with after blows and falls upon the head, sometimes associated with fracture of

the skull, sometimes with brain bruising, sometimes with both, at other times with neither. They give rise to no symptoms which are pathognomonic, or which even suggest, with any definiteness, their presence. The symptoms as coma and paralysis, which they excite, may be delayed for an indefinite period, and are liable to intermissions dependent upon recurrence of hæmorrhage, or in old cases upon the more or less rapid absorption and effusion of the cyst fluid. Even when immediate symptoms of compression occur, neither the nature of the accident nor the character of the injury to the head affords any clue whatever to the exact locality of the blood. Nor does the apparent slowness of the hurt, or the entire absence of symptoms, exclude the probability of meningeal apoplexy; neither is there any evidence to show that the evil consequences of these extravasations are hastened or delayed by the observance or otherwise of absolute rest, regulated diet, and medicinal treatment, after the accident which has caused the hæmorrhage. This is much to be regretted; for although in many cases surgical interference would be useless, yet in others could we with certainty tell the exact situation of the effused blood, the well-timed employment of the trephine might make all the difference between restoring the patient to health on the one hand, and of early death from compression, or prolonged years of constant headache, impaired senses, altered disposition, epilepsy, and even insanity, on the other.

To the surgeon, moreover, these inter-arachnoid effusions have a very important medico-legal bearing, for he may be called upon to express an opinion as to whether the hæmorrhage is the result of violence or not; and the life of an accused person may largely depend upon the surgical evidence. Now, as it is with regard to the source of the hæmorrhage and the condition of the extravasated blood, so is it with regard to the cause of the hæmorrhage. There are cases in which there is scarcely room for doubt, but there are others in which opposite opinions might plausibly be advanced. Extravasations of blood in the arachnoid occur from injury, but, as Mr. Prescott Hewett has said, they "are generally met with in cases where there has been a decided determination of blood to the head by whatever cause produced. I have met with them in cases where there has been great anxiety of mind, in poisoning of opium, in drunkards, in delirium accompanying phthisis, in maniacal patients, and in aged people, in whom I think these effusions depend oftentimes upon the atheromatous deposit in the arteries of the brain and its membranes."<sup>2</sup>

In the Guy's Hospital Reports for 1859<sup>3</sup> Dr. Wilks has reported in abstract eight cases of sanguineous meningeal effusion (apoplexy), in some of which the extravasation into the arachnoid cavity was certainly spontaneous, the result of Bright's disease or anæmia, in others as certainly due to a blow; whilst in others the cause was dubious, because, though violence had preceded death, there was such a diseased condition as might of itself have given rise to the hæmorrhage.

In dubious cases two questions may be raised in defence of a person accused of murdering the subject of an inter-arachnoid hæmorrhage. 1st. Was not the hæmorrhage the result of a diseased state of the blood or tissues of the deceased, or of over-excitement? 2nd. If disease or excitement was not the immediate cause of the hæmorrhage, was it not a strong predisposing cause, and would the same amount of violence have excited fatal hæmorrhage in a perfectly healthy person?

No question of the sort arose in the case I now am going to relate, because the scalp wound was caused by a fall, but had it resulted from a blow or from something thrown at the deceased, with intent to injure him, one or both of these questions would have been put to the surgeon. And like so many other questions, it would have been much easier to put than to safely answer them.

CASE 1. *Scalp Wound, Delirium Tremens, Extravasation of Blood into the Arachnoid Cavity; Death.*—James J—, aged thirty-one, was admitted into Brodrip Ward on 14th of December, 1881. He had been spending a fortnight in dissipation at Brighton, during which he was more or less drunk (generally more) every day. On the morning of December 14th he arrived in London, staggered along Oxford-street to Regent's-circus, where he fell heavily, striking the back of his head against the kerb. He was

<sup>1</sup> Vide Prescott Hewett, *Med. Chir. Trans.*, vol. xxviii., p. 67; and Wilks and Moxon, *Pathological Anatomy*, p. 197. No. 3089.

<sup>3</sup> Series III., vol. v., pp. 120, et seq.

picked up in a half-conscious state, taken to the police-station, and subsequently brought to the Middlesex Hospital. On admission, he was in a very muddled state of mind, and smelt strongly of drink. There was a small scalp wound, slightly to the left of the occipital protuberance; it did not extend to the periosteum. His pupils were regular and acting; his respiration and pulse natural; there was no symptom of any fracture of the skull. The stupidity of manner which was attributed to alcohol passed off after several hours, and for the next three days he lay quietly, perhaps drowsily, in bed. All this time he remained quite sensible, answered questions readily and intelligently, though in a rather subdued voice, and gave a very clear, though a most discreditable, account of his recent proceedings. He looked pale, took very little of the milk and beef-tea diet to which he was limited, and complained of frontal headache and double vision. On the morning of December 17th, he was sick, complained of having passed a very restless night, and appeared to be on the verge of delirium tremens. Later on the same day the symptoms of delirium tremens became marked, and he was removed to the delirium ward. The urine voided this day was examined, and found free of albumen. He was treated as all cases of delirium tremens under me are—viz., no opium was given, no undue or irritating restraint allowed, but enemata of two ounces and a half of strong beef-tea, with half an egg, were to be administered every three or four hours if he refused to take sufficient by the mouth. For fifty-eight hours he continued delirious, talking a good deal and having illusions. His other symptoms were subsultus tendinum, small and very compressible pulse, a moist, furred tongue, and clammy skin. He was very tractable, and neither violent nor noisy. At the end of fifty-eight hours he slept soundly and for a long time. On the morning of December 22nd he was brought back into the general ward, and seemed quite well, though weak. So he continued, and on Christmas-day he went to the church service; but he complained of feeling rather drowsy, and of having pain in the back, for which a liniment was ordered by the house-surgeon. During the night the nurse noticed how restless he was. After a time, however, he fell asleep, and in the morning (Dec. 26th) it was impossible to wake him, and he was found to have passed his urine in the bed. At 10 A.M., when seen by the house-surgeon, he was lying in a comatose state, with unequal pupils, the right being widely dilated and the left very much contracted; neither pupil responded to light, and the conjunctivæ were insensible. The pulse was 100, very small, and jerky. The skin was acting freely. There was slight twitching of both upper limbs; but it was very slight, and if more marked on one side than the other it was on the left. There was neither hemiplegia, paraplegia, nor facial palsy. At 1.30 P.M. he was in the same condition; the urine had all been passed into the bed, but two ounces of highly coloured urine were drawn off by the catheter, and was found to be nearly solid on boiling. The pulse was 100, and very small; temperature 101° 6'. There was no oedema around the scalp wound, but a little purulent discharge from it. Firm pressure about the wound produced no symptom. At 7 P.M. one-eighth of a grain of pilocarpin was given by hypodermic injection, and in less than half an hour the patient was perspiring profusely. At 8.30 P.M. five grains of calomel were given in butter placed at the back of the tongue. He sweated freely all night, and the bowels acted several times, and abundantly. On the following morning (Dec. 17th) he was better; he answered when spoken to, and he could swallow beef-tea and milk. The pupils were unequal, as before, but the conjunctivæ were sensitive; there was less stertor, but otherwise the respiration and the pulse were the same. The temperature kept above 100° F. The urine was still very highly charged with albumen. The hot-air bath was employed at 1 P.M., and at 2.30 P.M. half a drachm of compound jalap powder was taken by the mouth. During the following day (Dec. 28th) and the early part of the day after (Dec. 29th) his general condition was about the same, but the quantity of albumen had diminished, and was now about half. Later on the breathing became more stertorous again; he could neither speak nor swallow; the pupils were still inactive and unequal, the right being dilated and the left contracted. At 9 P.M. the temperature shot up to 104° 2' F., and at 3.10 A.M. the following day (Dec. 30th) he died.

*Autopsy.*—The post-mortem examination was made by Dr. Fowler twelve hours after death. The following is an abstract of his report:—The body was well nourished. There was considerable post-mortem congestion. To the left side of

the occipital protuberance there was a wound dividing the integuments, but not laying bare the bone. The wound was oblique in direction, one and three-quarters of an inch in length, and slightly irregular. The tissues around the wound were infiltrated with a little blood for about an inch in each direction. The tissue of the ventricles of the heart was pale but firm, but there was a considerable quantity of sub-pericardial fat. The mitral valve was thickened and fibrous at the edges, but competent. The aortic valves were competent; there were some spots of atheroma just above the attachment of the valves. The lungs were emphysematous, and there was a good deal of hypostatic congestion. The liver was moderately congested, and spleen was normal. The kidneys were large, and the capsules in places adherent; beyond swelling of the cortex, possibly from slight infiltration, there was no evidence of disease. The ureters were normal and the bladder healthy. On removing the calvaria, which was thick and very dense, no fracture could be found, nor was there any fracture of the base. The right half of the dura mater covering the convexity of the brain appeared somewhat distended. On reflecting this half of the dura mater blood-clot was found spread out beneath it. The clot was most abundant over the frontal bone and in the anterior fossa, but there was also a considerable quantity beneath the parietal eminence and over the occipital convolutions. The ascending frontal and the parietal convolutions were depressed and flattened. The blood was of a mahogany tint, the coagula were soft and adherent to the under-surface of the arachnoid covering of the dura mater. The source of the hæmorrhage could not be ascertained, but probably it was from a vessel behind the upper end of the right ascending parietal convolution. The dura mater separated easily from the bone. There was a small clot on the left side, immediately beneath the wound, which had compressed the occipital convolution over an area the size of a shilling. There was a small amount of extravasation within the meshes of the pia mater over the left half of the cerebrum. The venous sinuses contained some black clots. The arteries of the base were normal. The substance of the brain appeared normal, except that the depressed convolutions were pale. The left lateral ventricle was considerably dilated, the posterior horn reached three-quarters of an inch further backwards than the right ventricle.<sup>4</sup> There was no blood below the tentorium. The cerebellum was normal.

In this case the scalp wound was not accompanied by a fracture of the skull, nor by lesion of the brain substance, nor was the effusion of blood most extreme beneath the seat of the wound, or the supposed source of the bleeding on the diametrically opposite point to the scalp wound, as might be expected if caused by counter-stroke. Moreover, the man was a drunkard, and had just previously to the injury undergone a prolonged debauch, whilst a few days subsequently he had suffered from an attack of delirium tremens. Then followed two or three days of apparent convalescence. These points might have furnished a strong case in favour of the theory that the injury had nothing to do with the cause of death, and that the extravasation occurred either before the injury, as the result of the congestion of drunkenness and excitement, or after it as the immediate effect of delirium tremens. Nor would the character of the blood-clots have disproved any of these suppositions. Their colour and consistence corresponded, doubtless, with the date of the injury—viz., sixteen days before death; but the changes in effused blood vary with the locality and with many other conditions, and are neither so regular nor so accurately known as to justify anyone in asserting that the age of the clots could not have been eighteen, twenty, or even twenty-five days on the one hand, or ten or twelve days only on the other. The late Dr. Taylor exposed the fallacy and danger of relying too much on the state of the blood as a means of ascertaining the length of time it has been effused. Two men were tried at Derby in 1859 for manslaughter. Within fourteen days after the assault the injured man was convalescent, but in four weeks more he was dead. The prisoner's counsel asked the witness—"I can produce evidence to show that deceased fell down some steps into a cellar, upon his head, three weeks before his death. Do you not think it more likely that death was the result of this fall rather than of the beating three weeks prior to the fall?" The surgeon at once said

<sup>4</sup> Possibly in this condition we have the explanation of the contracted left pupil, the distortion of the ventricle by traction keeping up irritation of the third nerve. The dilatation of the right pupil was doubtless due to pressure by the blood-clot, which flattened the cerebral hemisphere.

"Certainly not; there could not have been the effusion of lymph I describe after an accident in so short a space of time as three weeks." As Dr. Taylor remarks, reasons justifying such a strong opinion were not forthcoming, and he goes on to prove by another case that there was nothing in the description of the clot in question to show that the effusion had taken place more than three weeks before death.<sup>5</sup> This and other cases quoted by Dr. Taylor warn us how unwise it is to dogmatise on this subject. But, it might be urged in opposition, there was no Bright's disease, no anemia, no disease of the vessels of the brain or its membranes, in this man; and, though there was no fracture of the skull and no bruising of the brain, there was a little blood effused beneath the seat of the scalp wound, and the most extensive effusion was in the situation where it would be looked for if caused by contre-coup. Moreover, it might be added, there was frontal headache and double vision. Such points should, of course, be allowed their proper weight, for they are of considerable significance in making up one's mind as to the more probable cause of death. But they do not dispose of the facts (1) that blood poisoned by alcohol may produce much the same effects as Bright's disease—e.g., the convulsions of renal disease, and the epileptiform convulsions of intoxication;<sup>6</sup> and (2) that the prolonged toxic effects of alcohol may produce a diseased condition of the brain and its membranes such as will lead to the occurrence of epilepsy, delirium tremens, or hæmorrhage even during the periods of comparative or entire abstinence from drink.

What I have desired to point out by these remarks and by this somewhat extraordinary case is:—1. That spontaneous effusions into the cavity of the arachnoid—i.e., effusions of blood from disease or excitement—are very often not distinguishable from traumatic effusions. 2. That post-mortem examination does not always explain the cause or the source of the effusion, and that the state of the blood-clot is only a very rough test as to the age of the effusion. 3. Extravasation of blood between the dura mater and bone, as also extravasations beneath the visceral arachnoid, accompanied by brain bruising, are almost certainly traumatic, whether fracture co-exists or not. Extravasations into the substance of the brain and into the ventricles are almost certainly spontaneous when no fracture and no brain bruising co-exists, and are probably so even when fracture without bruising of the cerebral surface is found. 4. Spontaneous effusions may occur without there being any naked-eye evidence of disease of the cerebral or meningeal vessels. 5. Spontaneous effusions into the arachnoid cavity from disease or excitement have occurred as early as the twelfth year of life, and at all ages subsequent to puberty. Inter-arachnoid hæmorrhage occurs at any age from violence. 6. In slight injuries to the head, such as small scalp wounds without fracture of the skull, or bruising of the surface of the brain, the surgeon should be extremely cautious in attributing inter-arachnoid extravasation to a blow, and more especially when, as in the above case, the injured person is of intemperate habits.

## RUPTURE OF THE URINARY BLADDER.

By WALTER RIVINGTON, F.R.C.S. ENG.,  
SURGEON TO THE LONDON HOSPITAL.

### PART III.—(Concluded)

#### REPORTED CASES OF RECOVERY AND TREATMENT.

APART from the objections which can be urged against the genuineness of the recorded recoveries after intra-peritoneal rupture of the bladder, there is one circumstance which would quite justify us in setting the cases on one side in considering the question of treatment; and that circumstance is the remarkable fact that if the genuineness of all the eight cases were to be admitted the effect in regard to the selection of the best method of treatment would be thoroughly bewildering. The record would show four cases of recovery after the use of the catheter only; one case of recovery after "washing out the peritoneal cavity" by means of the catheter passed through the rent in the bladder; one case

successfully treated with the aspirator; one case of recovery after lateral lithotomy; and one case of recovery after abdominal section, sponging the urine and blood from the peritoneal cavity, and leaving the rent to itself. The inference would be drawn that one mode of treatment is as good as another, and this "lame and impotent conclusion" would sadly mar the prospect of attaining an effectual means of dealing with a most fatal lesion. Turning, then, to the accounts of the cases which are beyond the reach of doubt, we may affirm that in neither form of rupture—the intra-peritoneal or the extra-peritoneal—can reliance be placed on constitutional and general means of treatment. Leeches, venesection, fomentations, clysters, purgatives, sinapisms, salines, poultices, calomel, opium, morphia, &c., probably affect the ultimate issue as little as the fresh sheepskins applied to the abdomen of the patient whose case is related by Bonetus, and the oxyrhodinum with which the parts were subsequently smeared. Morphia and opium may be very efficacious in relieving suffering, but, uncombined with surgical measures, they have no power to do more than promote the euthanasia. If any hope is to be entertained, it lies in the prompt application of efficient local treatment. The main indications are two—first, the removal, as speedily as possible, of the effused urine, and, secondly, the prevention of the further escape of urine through the rent in the bladder into the connective tissue, or the peritoneal cavity. For these purposes the means at the disposal of the surgeon are catheterism, intermittent or permanent, washing out the peritoneal cavity, and retaining a catheter in the bladder, paracentesis abdominis or simple incision to evacuate the urine, perineal sections, median or lateral, as for stone in the bladder, tapping the recto-vesical cul-de-sac, and abdominal section, combined or not with sewing up of the wound in the bladder, and the establishment of drainage.

1. By the use of the catheter only it is possible to draw off a considerable portion of the urine effused into the peritoneal cavity, if the rent happens to be on the posterior wall of the bladder, but it will not remove all of it; and when the rent is in another part of the viscus it may fail to remove any, whether from the peritoneum or connective tissue. If passed only at frequent intervals, it will not altogether prevent further extravasation, and is liable to disturb the process of repair. Retention of a catheter in the bladder is more efficacious in preventing effusion, but it is not thoroughly reliable, and the patient finding it intolerable, may remove the instrument in the absence of the medical attendant. It is no wonder, then, that as catheterism alone does not fulfil the necessary indications, it should have been "weighed in the balance, and found wanting."

2. *Washing out the peritoneal cavity*, as in Thorp's case it was euphemistically termed, by means of a catheter fitted with an indiarubber bag and stopcock, has been strongly recommended by Mr. Heath on the basis of its supposed success in the hands of Dr. Thorp, and the failure of abdominal section in his own and Mr. Willett's cases. I cannot say that I entertain any well-grounded hope that it will prove efficacious in removing the extravasated urine, neutralise its evil effects; it appears to me to be a fallacy to suppose that the complicated peritoneal cavity can be washed out as a simple circumscribed cavity like the bladder can be washed out through a catheter alone. For effectual washing out an opening should be established into the peritoneum above the pubes, whereby the danger of merely driving the urine further amongst the intestinal coils would be obviated. A solution of thymol would be better than warm water for this purpose. Certainly such a case as Dr. Thorp's should not lead the surgeon astray from the employment of more active measures when he is at liberty to act as his judgment directs.

3. *Tapping the recto-vesical cul-de-sac* was suggested by Dr. Harrison as a means of treating intra-peritoneal rupture under the mistaken impression that the urine frequently collects and is confined in that pouch, and that a dependent opening into the rectum would efficiently drain the peritoneal cavity. I agree with Mr. Spence that the procedure would be uncertain and often dangerous.

4. *Paracentesis abdominis* has been performed twice in intra-peritoneal ruptures (cases of Bonetus and Cusack). A cutting instrument is to be preferred to a trocar and cannula. This operation is not likely to prove sufficiently efficacious by itself, but it might be practised for the confirmation of a doubtful diagnosis, as a preliminary to abdominal section, or as a substitute for it when a more effectual procedure was

<sup>5</sup> Taylor, A. S., *Medical Jurisprudence*, 1865, p. 530.

<sup>6</sup> Vide Dr. Robertson's evidence in a recent trial for murder at Glasgow.

forbidden. In extra-peritoneal ruptures incisions must be made freely wherever urine can be evacuated.

5. The operations of *median and lateral lithotomy or cystotomy* are of unequal value. The median operation consists merely of urethrotomy and dilatation of the prostatic urethra, and, as the sphincter soon regains its retentive power, can scarcely be effectual, either for the removal of urine already in the peritoneal cavity, or for subsequent drainage. For exploration it would be simple, safe, and valuable, and in cases complicated by stricture the best method of preliminary procedure. (Compare cases of Arnott, Clark, Dickinson and Holmes, Earle, Quain, Reginald Harrison, and Robert F. Weir.) In *lateral cystotomy*, on the other hand, the knife would be able to cut freely into the prostate and reach the neck of the bladder, which would be slow to regain its retentive power. This constitutes the great recommendation of the lateral operation, and no other measure appears to equal it for efficiency in this important direction. By itself it could scarcely have much effect in removing urine already effused into the abdominal cavity, and for this purpose some supplementary procedure would be necessary. It is also difficult to understand how the operation could be effectual for the removal of urine which had already escaped into the pelvic fascia through an extra-peritoneal rent, but probably it might answer the purpose for extra-peritoneal ruptures immediately behind the prostate, if the operator had the boldness to carry his incision through the gland and its capsule. In a case of intra-peritoneal rupture Mr. Partridge cut into the bladder and found it empty. The procedure has been strongly advocated by Dr. Stephen Smith and Dr. John A. Liddell<sup>2</sup> in America, and by Mr. Bryant in England.

6. *Abdominal section and sewing up the rent in the bladder* were discussed by Benjamin Bell and warmly advocated by Dr. Blundell,<sup>3</sup> who made experiments on rabbits to determine the value of his suggestion. In 1851 Dr. Gross proposed abdominal section for the removal of the effused urine, and more recently Mr. Holmes has written in favour of the procedure combined with suture of the bladder. Mr. Willett<sup>4</sup> and Mr. Heath<sup>5</sup> have put this method in practice without saving the patients. The causes of failure are not far to seek. In Mr. Willett's case there was a delay of twenty-four hours, the incision was five or six inches in length from the umbilicus to the pubes, the intestines were much exposed, and the suture was proved at the post-mortem to have been defective. In Mr. Heath's case the interval before the operation was unavoidably longer than in Mr. Willett's case; some clotted blood was left in the pelvis and the catgut suture gave way. The incision, however, was only two inches long. But though Mr. Heath's patient died, the advantage of abdominal section is strikingly demonstrated by the great relief afforded to the patient. My second patient, who was treated only by the intermittent use of the catheter and opium, lived six days; but how remarkable the contrast between his suffering restless state, with incessant vomiting, and the condition of Mr. Heath's patient, almost free from pain, entirely free from sickness, passing quiet nights and days, and dozing with limbs outstretched. Abdominal section has not yet been fully and fairly tried. A series of twenty or thirty cases may be needed before the value of the method can be determined. Much will depend on points of detail, the promptitude of application, the age and condition of the patient, and severity of the injury, the more or less complete removal of urine and blood from the peritoneal cavity, the length of incision, the treatment of the wound in the bladder, washing out the peritoneum, and the establishment of drainage. It is unnecessary to insist on the earliest possible formation of a diagnosis and performance of the operation, and a thorough removal of blood and urine from the peritoneal cavity. Few will dispute the less severity of an incision two or three inches long compared with one of twice the length. Experience alone can determine whether the wound in the bladder should be sewn up or not. If we could unreservedly trust to the genuineness of Dr. Walter's case, the rent might be left to take care of itself, and we might find some justification for this in the frequently jagged and contused edges of the aperture, which render primary union unlikely to occur. Dr.

Vincent,<sup>6</sup> in a brochure for which I am indebted to Mr. Heath, has recently advocated cystorraphy by a combination of two kinds of suture termed the sero-muscular and serous suture respectively. In his experiments on dogs he found that abdominal section and cystorraphy were uniformly successful when practised within eight and a half hours, but constantly failed through urinary intoxication when performed twenty-four or twenty-five hours after the bladder was wounded. He attributes the failure of Mr. Willett's and Mr. Heath's cases to the length of time which elapsed before the operation, and to the ineffectual character of the suture. He deprecates founding any canon for treatment on Dr. Thorp's case. Mr. Heath is convinced of the inutility and harmfulness of a drainage-tube passed through the abdominal wound into the pelvis, but he seems to regret that he did not pass a tube through the recto vesical pouch of peritoneum and the wall of the rectum, bringing it out of the anus. I feel very strongly that this would be a dangerous procedure, and that the risk of gas getting into the peritoneal cavity would far outweigh any advantage arising from the dependent opening. If another opening be needed, and I am inclined to think that it is, the most efficient means of securing free exit of urine and giving perfect rest to the bladder would be to combine lateral lithotomy or cystotomy with abdominal section, performing the abdominal section first with antiseptic precautions, sewing up the rent in the bladder, if it ought to be sewn up, and afterwards making the perineal opening. Doubtless the combined procedure may appear severe, but an intra-peritoneal rent in the bladder is a desperate injury requiring to be met not by desperate but by thoroughly effectual measures, directed first to the removal of urine already extravasated, and, secondly, to the prevention of further escape. Surgery will achieve no unimportant triumph if occasional recoveries can be ensured by improved methods of treatment.

#### CLINICAL OBSERVATIONS ON

### THE TREATMENT OF ENLARGED TONSILS.

By GORDON HOLMES, M.D.

1. *Excision*.—That excision is the most fitting remedy for enlarged tonsils is a proposition from which few authorities or none would now be found to dissent. The theory, however, that removal of the tonsils has some adverse effect on the generative system has gained some currency amongst practitioners. Those who practise the throat speciality will scarcely attach any importance to this hypothesis, as they have the opportunity of observing numerous cases of females who have borne large families, although the tonsils were excised in youth.

The condition of the tonsils at the time of operating is a point which deserves attention. As a rule, when the patients first present themselves, the organs are in a state of acute or subacute inflammation, which is the immediate cause of treatment being sought. Under these circumstances, some practitioners are in the habit of operating at once, whilst others wait until the tonsils have regained their ordinary condition of indolent chronic enlargement. In order to decide this question, the arguments to be drawn from clinical observation are rather in favour of delay. It is no doubt well for the patient to be relieved at the soonest from the diseased glands, and the excision, with the attendant hemorrhage, may abridge, or render abortive an attack of quinsy. If, however, the tonsillitis is very acute, the pain of the operation may be excruciating, and it may even be difficult to open the mouth wide enough for the accurate introduction of the instruments. But the most important consideration is that after the inflammation has subsided, and a few weeks have been employed in general tonic and local astringent treatment, the tonsils may return to nearly their natural size. Of course should the history of the case indicate clearly a permanent hypertrophy, we need not hesitate to operate immediately when other circumstances are favourable. It is, indeed, by no means uncommon to see even cases of mild subacute or chronic tonsillitis, in which a considerable swelling undergoes spontaneous involution in

the course of a month or two, according as the general health improves. Such instances are very likely to mislead the practitioner into the belief that a cure has been wrought by the aid of some really impotent local application. It is also interesting to observe that in a series of such attacks, where the subsequent involution is always less and less complete, we can perceive the origin of chronic tonsillar hypertrophy. And most probably there is no other way in which the disease arises, unless in those cases where the enlargement is apparently congenital.

With respect to the method of operating, the tonsillotome has almost superseded the bistoury and tenaculum, owing to the ease and rapidity with which it can be used, and the little suffering it causes the patient. The rare case of a tonsillar calculus alone remains in which the tonsillotome is inapplicable. The instrument known as Physick's is preferred by some, that of Fahnstock by others, the majority; both models being of American invention. Physick's pattern has the advantage of allowing more force to be applied in fixing it firmly on the tonsil, as it is grasped by a stout handle, whilst the convex cutting-blade can also be pressed down with great power by the thumb. Fahnstock's, on the other hand, is an instrument to be employed with dexterity rather than force, as it is manipulated by the thumb and first two fingers only, each of which is accommodated with a separate ring. It is, however, a much surer instrument than Physick's, which often fails to excise the tonsil, even in the hands of the most practised operators. This is mainly due to the aptness of the convex blade, which enters at one point only, to press the tonsil outwards, and glide over or merely lacerate its surface, even when sharpened to perfection. The tonsil is, in fact, often very gummy, and requires to be jammed very firmly against the blade in order to be cut directly through. But the lunated edge of Fahnstock's cutting ring is much less likely to swerve from the straight course, as it begins by being in contact with the whole surface to be incised, whilst the organ is steadied and drawn into the tonsillotome by the transfixing prong.<sup>1</sup> As Fahnstock's instrument is therefore almost certain never to miss the tonsil, it is more under the command of the operator, so that a larger or smaller portion can be removed according to the requirements of the case; whereas in using Physick's, owing to the necessity of fixing it as deeply and firmly as possible over the tonsil, the amount to be taken must mainly be left to chance. For the practitioner who seldom has occasion to excise the tonsils, Fahnstock's is decidedly the model to be recommended. In all cases it is advisable to support the tonsil during the operation from the outside of the neck, either by the hands of an assistant or by grasping the throat in a fork formed by the left thumb and forefinger of the operator.

As regards hæmorrhage after tonsillotomy, it is usually very trifling and ceases spontaneously in a few minutes, or after gurgling with cold water. In rare cases (probably about 1 per cent.) it is troublesome and must be controlled by ice and strong styptics. Considered in this relation the tonsillotome is safer than the bistoury, as the dragging of the tenaculum displaces the parts so that the knife may inadvertently cut deeper than intended by the operator.

2. *Caustics*.—Although excision is the standard remedy, cases are constantly met with in which the patient or his relatives, if a child, steadfastly refuse to permit the performance of the operation. Frequently also it happens that the enlargement is not so pronounced as to render the excision strictly necessary. It is of great importance therefore that we should be in possession of some mild measures, which, aided by time, can effect a reduction of the tonsils. For the purpose astringents (such as strong solutions of perchloride of iron, chloride of zinc, &c.) or caustics are our only resource; but the former, however useful in promoting spontaneous resolution in cases of temporary subacute engorgement, are totally powerless in the face of a true hypertrophy. Hence the only means that can be adopted with any clear prospect of success is to destroy small portions of the tonsils in slow succession by repeated cauterisations carried on for a lengthened period. This object is generally carried out by the application of solid nitrate of silver, chloride of zinc (in the stick), Vienna paste, London paste,<sup>2</sup> or the galvano-caustic to a limited area of the surface of the tonsil every two or three days. Of these remedies the nitrate of silver is very valuable when the

superficial substance of the gland is in a softened and raw state, as it can be rubbed freely over the whole organ, usually without causing any suffering to the patient; but it is of slight avail in reducing the volume of the toughened mass of connective tissue which generally constitutes the bulk of the permanently enlarged tonsil. Nor can it be said that the stronger caustics are much more potent in this way, for they can only be used in this position so as to destroy very minute portions at a time, and hence the progress is mostly so slow and tedious that few patients will persevere until positive results have been attained. If any exception can be made to this statement, it must be in favour of the galvano-caustic<sup>3</sup> (a small loop of wire raised to a white heat by electricity as soon as placed in contact with the surface to be cauterised), for it kills immediately the part touched and leaves a clean ulcer, which soon heals almost unfeeling by the patient. On the other hand, the London paste, &c., often give rise to considerable congestion round the sloughing point, attended with aching and pain on swallowing for many hours.

There is, however, another method, very much more effective, of applying the common caustics to the tonsil, which appears to have remained hitherto unnoticed. The tonsil, as the anatomist knows, is permeated by several rather large channels around which the follicles are collected, opening on the pharyngeal side of the gland, whence its characteristic cribriform aspect. Their orifices, about seven to fifteen in number, are sufficiently evident to be counted on the healthy tonsil *in situ*, whilst in the hypertrophied condition these lacunæ increase greatly in calibre and depth, and can be ascertained by a probe to vary from one-eighth of an inch to half an inch in length, with a diameter capable of admitting a style of ordinary size. These observations, then, afford a valuable indication for treatment: for through these natural canals a way lies open for us to attack the heart of the gland in a most efficacious manner with our caustics. Thin, pointed sticks of nitrate of silver or chloride of zinc can easily be pressed into the lacunæ and worked round for a few seconds. Small sloughs are thus formed which are soon discharged, and in the progress of this treatment the tonsils are hollowed out in one direction whilst being contracted into much smaller bulk by the subsequent cicatrization in another. Two or three channels in each tonsil can be cauterised daily or on alternate days, and we can thus act on a comparatively large surface whilst causing but slight external soreness and little or no suffering to the patient. In practising this method, although the stronger caustics may be used, I do not think it will be necessary to have recourse to anything more potent than nitrate of silver, which acts much more effectually on the more tender internal structures of the tonsil than when applied to the comparatively callous pharyngeal surface.

Finsbury-square, E.C.

## A CASE OF INTRA-ORBITAL ANEURISM

FOLLOWING

FRACTURE OF THE ANTERIOR FOSSA OF THE BASE OF THE SKULL AND MENINGITIS; LIGATURE OF THE COMMON CAROTID SIX DAYS AFTER ACCOUCHEMENT; EXTIRPATION OF EYEBALL; RECOVERY.

By WALTER E. LLOYD, L.R.C.P. ED. & L.F.P.S.G.

CASES of intra-orbital aneurism are of somewhat rare occurrence. Statistics show that the majority of the cases that do recover are those treated by ligature of the common carotid. A case recently reported by Dr. Wolfe of Glasgow, which had been operated on by that devoted surgeon, the late Dr. Foulis, adds another to the list of successful cases treated by this method. Although the case I am about to relate differs somewhat from Dr. Wolfe's, happily the same result was secured. In my case the aneurism was first intra-cranial, and then, progressing gradually through the sphenoidal fissure, became intra-orbital. The history of the case shows it to have been entirely traumatic.

Mary Jane W—, aged twenty-nine, the wife of a journeyman baker, on July 21st, 1881, was driving in a two-

<sup>1</sup> The prongs are sometimes fitted to Physick's model.

<sup>3</sup> Now coming into general use, chiefly owing to the advocacy of Dr. Capart of Brussels.

wheel cart with her husband, delivering bread in the country; while returning home through the village of Long Ashton the horse fell down, and the man, his wife, and a child were all thrown out on to the road; the man and the child were uninjured, but the woman pitched on to the left side of her head. I happened to pass the scene of the accident about five minutes after, and was requested to attend to the injured woman. She had been lifted into the cart and I found her in a semi-conscious condition, bleeding slightly from the nose. I ordered her to be at once removed to her home, and shortly after went there and was able more thoroughly to examine her. I found her in bed lying on her back with symptoms characteristic of concussion. When spoken to loudly she opened her eyes and attempted to answer, but was unable to do so. The bleeding from the nose still continued; there was subconjunctival ecchymosis of both eyes, but most marked on the left side; the pupils were normal and acted when stimulated by light. I ordered her to be kept on milk and beef-tea. I found her to be six months pregnant. The next morning symptoms of meningitis appeared, and by the evening (twenty-four hours after the accident) she was in a state of violent delirium, the assistance of three or four persons being required to keep her on the bed. I ordered the head to be shaved, and an ice-cap applied. The bleeding from the nose had ceased, but the subconjunctival vessels were very much gorged with blood, those of the left side being somewhat more so than the right. The delirium continued for three days, when she gradually recovered consciousness, and from that time she made good progress. I kept her in bed, and after about six weeks it was noticed that the left eyeball was becoming more prominent. She found the sight was going from the left eye, and complained of a loud whirring, "like the noise of a mill," in the left ear, also of deafness on the same side. It became at length evident that these symptoms were due to an intra-orbital aneurism. On applying the stethoscope, a loud bruit was heard over the frontal and left temporal bones, and there was distinct pulsation of the left eyeball, both of which ceased when the left common carotid was compressed.

Now arose the question of treatment, and the complication of her being seven and a half months pregnant was a grave one. In consultation with two of my surgical friends, it was decided that it was best not to attempt an operation until after accouchement, but to keep her in bed, give ten-grain doses of iodide of potassium three times a day, and when the labour came on to deliver her as speedily as possible, so as to avoid the consequences of straining during labour; this was the treatment adopted up to the time of her confinement.

On Oct. 14th I was sent for at 9 A.M., and attended immediately. I found she had been in labour about two hours, the os uteri was dilated as large as a crown, the pains were forcing, and as I found the head did not make speedy progress, I at once applied the long forceps, and delivered her in a few minutes of a remarkably large living male child. The prominence of the eyeball was not affected by the labour.—15th: Doing well, the condition of the eyeball not altered at all.—16th: Doing well as regards the confinement, but complains of great pain in the head, and that the noise is much louder than it has been hitherto; the conjunctiva is much more injected, and the eyeball more prominent. Ordered iodide of potassium and bromide of potassium, ten grains of each, every four hours.—17th: The protuberance of the eyeball much increased, as is the oedema of the conjunctiva. She cannot sleep, the pain and noise in the head are also increased.—18th: All the symptoms are still more aggravated. Pulsation very marked, and the eyeball still more protruding; the sight is now quite gone from this eye.—19th: The prominence of the eyeball still much more increased, and the oedema of the conjunctiva much more marked, projecting one-eighth of an inch beyond the cornea; cannot distinguish light from dark. Says the pain in her head will drive her mad. Pulse weak, about 60; temperature normal; going on well as regards the confinement. I was sent for hurriedly at 8 P.M., as it was thought she was dying. My friend, Mr. W. H. Harsant, surgeon of the Bristol Royal Infirmary, saw her in consultation with me, and we decided that the only chance of saving her life was to ligature the common carotid. She was then very faint; anxious expression of countenance. Pulse hardly perceptible. Ordered brandy, and the following mixture—tincture of opium, ten minims, with compound spirit of ammonia, twenty minims, every four hours. Owing to the extreme deli-

cacy of the operation, and the many difficulties which presented themselves, there being no gaslight and having no assistants, &c., we postponed the operation until the following morning, hoping also that she might be better able to take the chloroform.—20th: Her condition is slightly improved, the pulse being somewhat stronger. Chloroform having been administered by Mr. Harsant, whom I cannot sufficiently thank for his very valuable assistance, I proceeded to ligature the common carotid. Making an incision three inches and a half in length along the anterior border of the sterno-mastoid, and carefully dissecting, I divided the different layers of tissue on a director. There was no special feature in the operation, except that the artery was overlapped by the internal jugular vein, which had to be drawn aside by a retractor, the carotid being found directly underneath it. The needle, being carefully passed from without inwards, was then threaded with a stout carbolised catgut ligature, which having been tied and the ends cut off short, the wound was brought together with six horsehair sutures, and covered with boracic lint. I was most ably assisted by Mr. W. A. Jones and Mr. H. M. Powell, students of the Bristol Medical School. During the progress of the operation there was very slight hæmorrhage, one small vessel having to be secured by torsion. 7 P.M. (four hours after the operation): Frequent vomiting from the chloroform. Ordered ice to suck. Says she feels much better; the pain in the head is much less, and the whirring noise is gone. The oedema is already much less, the pulsation has disappeared, and the bruit cannot be heard. She says that now she can see me quite distinctly.—21st: Has been vomiting during the night. The bruit is slightly audible; there is no pulsation. She says she has been much relieved by the operation, and feels quite different. The wound is looking healthy, but there is some pain at the top of the head (neuralgic). Pulse 80; temperature normal.—22nd: The vomiting has ceased. She still complains of the neuralgic pain. About three drops of pus came from the lower end of the wound when I dressed it to-day, but it is looking healthy. Pulse and temperature normal.—23rd: Mr. Harsant saw the case with me to-day. There is a most marked improvement; the protrusion of the eyeball is rapidly receding, and the fold of the eyelid is seen when the eye is open; the sight is perfect, the oedema of the conjunctiva is much less, and she is able to use the muscles of the eye, and rotate it on any axis. The wound is looking healthy, but, as there is some pus coming from the lower end, I removed the lowest suture, and about a drachm of pus exuded. Otherwise she is doing remarkably well. The bruit is still slightly audible.—24th: The oedema of the conjunctiva very much less. I removed the last three sutures from the wound, which has healed, except at the lower end, from which the pus escapes. Ordered fish diet. She says the whirring noise has almost gone. She was quite deaf on the left side before the operation was performed, but can now hear quite distinctly on that side. The prominence of the eyeball has most markedly decreased. There is now no pulsation, and the bruit is hardly perceptible. The wound completely healed after a few days.

The progress of the case has been somewhat remarkable. At times there has been acute pain in the head, referred to the back of the left eyeball, relief from which could only be obtained by large doses of opium. The sight of the left eye has become gradually destroyed, the crystalline lens has become opaque and the eyeball pushed forward by what appears to be a large organised blood-clot; the bruit is still heard very distinctly, but, whereas before the operation it was heard loudest over the orbit and temporal fossa, it is now heard loudest over the mastoid process and the occiput. The sight of the right eye being threatened by the condition of the left, I determined to extirpate the left eyeball.

July 6th: Mr. Harsant having kindly given chloroform, I extirpated the eyeball. It was with great anxiety that I commenced this operation, fearing that during its progress I might possibly cut into the aneurism and the patient die from hæmorrhage. Happily my fears were not realised; there was hardly any bleeding. After removing the eyeball I passed my finger carefully into the orbit and could feel a firm but somewhat elastic mass at the back. The wound rapidly healed. The patient has been into the country and has returned home in perfect health, and able to perform her domestic duties; she is about to have an artificial eye in the place of the one removed.

I believe this to be the first case reported in which the common carotid artery has been ligatured six days after a

woman's confinement. Although the operation was of so grave and complicated a character the result clearly justified the means, as this woman's life was undoubtedly saved by the operation. In conclusion, I would call attention to the rapid healing of the wound, notwithstanding the fact that the operation was not performed antiseptically.

Bristol.

#### A CASE OF

### EXTREME CYANOSIS IN AN ADULT, PROBABLY OF CONGENITAL ORIGIN.<sup>1</sup>

BY JUDSON S. BURY, M.D., 'B.S. LOND.,

HONORARY ASSISTANT MEDICAL OFFICER TO THE CLINICAL HOSPITAL AND DISPENSARY FOR CHILDREN, MANCHESTER.

MARY F—, aged twenty-one years, was quite well during infancy and childhood, the only ailment she ever had was an abscess in the thigh. Her mother states that she was not a delicate child, was not more easily tired than other children, and did not differ in colour or in any other respect from a healthy child. The blueness set in suddenly about two and a half years since. The patient had "hurried a good deal" and felt pains in the chest and back and a choking sensation, and the woman with whom she worked remarked that "she was as blue as a whimberry." The blueness disappeared the next day but returned in a few weeks, and has since persisted. Menstruation began shortly after the first appearance of the cyanosis. When the patient was between nineteen and twenty years of age she was regular for the first year; then the catamenia stopped for about nine months. They now occur regularly, but are very scanty. There is no family history of rheumatism, and the patient has never had pains in her limbs or other symptoms suggesting a rheumatic diathesis.

*Present condition.*—Patient is of short stature, being about 4 ft. 7 in. Facial expression somewhat dull; skin muddy and dusky; the lips are blackish-blue; the conjunctivæ injected and of a light-claret colour; nose and cheeks purplish; the tongue, inside of the mouth, and throat present a dark-purple, congested appearance; the ends of the fingers and toes are clubbed and livid; extremities cold; no œdema; the urine is high-coloured, deposits urates, and contains a trace of albumen. On inspection of the chest, a distinct bulging is visible; it involves the second, third, and fourth left rib cartilages; there is some tenderness over the sternum. The jugular veins are not distended, but there is distinct pulsation of the carotid arteries. The heart's impulse is diffused and heaving; it is felt in the third, fourth, and fifth spaces, as far out as the anterior border of the left axilla, but is not felt near the sternum, nor is there any epigastric pulsation. The maximum point of the impulse is in the fifth space in the nipple-line; no thrill. The cardiac dullness is much increased, and laterally rather than vertically, extending from about one inch to the right of the sternum to almost the middle of the left axilla; the third rib marks the upper limit of superficial dullness, though the first two spaces are higher pitched than those on the right side; the sixth rib is the lower limit. On auscultation a high-pitched, systolic, whistling murmur is heard at the base, of maximum intensity over the first piece of the sternum; it is well conducted down this bone, being also well heard at the right sterno-clavicular articulation, and faintly in the carotids. A vertical line from the middle of the left clavicle marks its extreme left limit, and the murmur is gradually lost as the stethoscope is moved towards the apex; it is not heard behind; the sounds at the left apex are quite pure. The second sound is accentuated over the pulmonary cartilage, and is louder than at the aortic cartilage. The pulse is regular in rhythm, but not quite regular in force; it is equal on the two sides, and is felt in the femorals and in other arteries.

*Remarks.*—The striking feature of the case is the comparatively sudden onset in an adult of intense and permanent cyanosis, unpreceded by any illness, and found to be associated with extensive heart disease. If the latter were the result of endocarditis entirely acquired after birth, we should expect to have marked signs of engorgement of the general venous system; indeed the absence of dropsy alone points strongly to some congenital malformation of the heart, and also proves

that cyanosis cannot be completely explained by the theory of venous congestion. The bulging of the chest may be taken as an indication that the enlargement of the heart occurred at an early period, when the chest walls are soft and yielding. By far the commonest cause of congenital cyanosis is contraction of the pulmonary artery as a result of foetal endocarditis; the first consequence of this contraction is hypertrophy of the right ventricle, the second a permanent communication between the two sides of the heart; and if stenosis is extreme it may prevent the closure of the ductus arteriosus. Thus there is compensation for the strain on the right ventricle; the venous blood passes into the aorta and is conveyed to the lungs either by enlarged bronchial or other arteries, or by a dilated ductus arteriosus. These safety valves prolong life and diminish or prevent cyanosis. In contraction of the pulmonary artery the duration of life varies directly, the cyanosis probably inversely, with the degree of patency of these foetal passages. It is now indeed well established that the mere intermixture of arterial with venous blood is not sufficient to produce cyanosis, the essential element for this condition being, as Dr. Lewis Smith puts it, the hindrance to "the free and regular flow of blood to, through, or from the lungs." The physical signs in the case before us are somewhat complicated. In pulmonary stenosis we expect indications of hypertrophy and some dilatation of the right ventricle, together with a basic systolic murmur of maximum intensity at the junction of the third left costal cartilage with the sternum, conducted towards the left clavicle and not audible in neck arteries. In the patient the murmur is loudest at the top of the sternum, is conducted to the right as well as to the left, and is heard in the carotids. There is increase of dullness to the left as well as to the right, and there is no epigastric pulsation, but a heaving impulse in the left mammary region. Most of these signs point to disease at the aortic orifice rather than at the pulmonary; but this as a result of foetal endocarditis is very rarely met with, not because (as Rauchfuss points out in Gerhardt's Handbuch) the aorta is less frequently affected with endocarditis than the pulmonary artery in foetal life, but on account of the very short duration of life, only one-eighth of the cases collected by Rauchfuss survived the second week of life, only one case the first month. Dr. Sansom, in a lecture reported in the *Medical Times* for 1870, relates a case of congenital stenosis of the pulmonary artery where the basic murmur had an aortic conduction. Although the aorta after death was found to be quite normal, he thinks that this was due to the coexistence of a hæmic murmur. Dr. Peacock says that the septum of the ventricles being usually defective when there is a considerable contraction of the pulmonary artery, "the aorta derives its supply of blood from both ventricles; and, if so, a systolic murmur may probably be produced by the meeting of the two columns of blood in the ascending aorta, which may modify the signs observed."

In spite, then, of aberrant physical signs, it seems probable that the origin of the pulmonary artery was affected with endocarditis in foetal life, that the effects of its obstruction were compensated for by the persistence of communication between the two sides of the heart, and, perhaps, also by a patent ductus arteriosus; and, according to Rauchfuss, the loud second sound at the pulmonary cartilage would favour a patent duct. But about puberty, as the body became more developed and the volume of the blood greater, the insufficiency of the heart first made itself apparent. It is possible, too, that a fresh endocarditis was lit up about this time, and affected the aortic valves, for, as Dr. West has pointed out, congenital malformations of the heart predispose to inflammation of the valves.

Manchester.

**PHOTOGRAPHY.**—An essential preliminary to the obtaining of a good photograph is that the sitter should be, as regards the different systems of the body, in a state of perfect tranquillity. But in London it is usually necessary that studios, in order that the requisite light may be secured, should be placed at the top of the house, and the exertion of going up several flights of stairs is not conducive to that quiescent state of the circulation so desirable in a sitter. This difficulty has been met in the new photographic rooms of Mr. Barraud of Oxford-street, by the provision of a patent lift, which, worked by a gas-engine, and constructed on the automatic stopping-gear system, conveys visitors in a pleasant and easy manner to the elegantly appointed studio aloft.

<sup>1</sup> Case shown at the Medical Society, Manchester, October 4th, 1882.

# THE FIRST FIVE YEARS' WORK AT THE LIVERPOOL SEAMEN'S DISPENSARY FOR VENEREAL DISEASES.

By FREDERICK W. LOWNDES, M.R.C.S. Eng.,  
AND

ARMAND BERNARD, M.B. Dub.,  
SURGEONS TO THE DISPENSARY AND TO THE LIVERPOOL LOCK HOSPITAL.

THAT merchant seamen suffer severely from venereal diseases is too well known to require proof. It is also well known that it is among them the advertising venereal quacks find many victims. These two circumstances induced the committee of the Liverpool Sailors' Home, upon our suggestions, to open in February, 1877, a self-supporting dispensary, in connexion with the home, for the treatment of venereal diseases among all seamen in Liverpool, whether British or foreign, and whether inmates of the home or not. It was decided from the commencement to limit the practice of the dispensary to cases of venereal disease, and that the dispensary should be self-supporting, each patient paying one shilling for each attendance, receiving for this advice and medicine. The result of the five years' working, ending December 31st, 1881, will be of interest, and may be an encouragement to those who advocate self-supporting dispensaries. The lock hospital here has twenty-five beds for male patients, which are constantly full; there is no outpatient department at it nor any of the general hospitals, except the Stanley Hospital, which is a long way from the Sailors' Home. The nearest general dispensary (the South) is also some distance off, and the hours of attendance are very inconvenient ones for sailors; hence the dispensary supplied a want without adding to free medical charities or doing any injustice to the latter. It also brought medical advice and medicine within easy reach of the sailors, whose nearest advisers had hitherto been the advertising quacks. We have restricted the practice of the dispensary as much as possible to men before the mast, though we occasionally see stewards, cooks, boatswains, carpenters, &c. Suitable premises were found contiguous to the Sailors' Home, and the dispensary was opened on February 26th, 1877. The following table shows the results:—

Year.	Patients.	Attendances.	Remarks.
1877	847	2363	Only ten months
1878	1002	3246	Whole year
1879	853	2823	Ditto
1880	944	3512	Ditto
1881	848	3276	Ditto
Total ...	4494	15,220	—

For the first year we were unable to keep so accurate a register of cases as we could have wished; but since Jan. 1st, 1878, a most careful and, so far as is possible, a most accurate register has been kept, from which we are enabled to give the following summary:—

	1878.	1879.	1880.	1881.	Total.
Simple sores ...	226	173	229	205	833
Gonorrhœa ...	364	321	330	294	1309
Gleet ...	200	169	184	136	689
Primary syphilis ...	112	101	115	107	435
Secondary syphilis...	95	83	79	96	353
Tertiary syphilis ...	5	6	7	10	28
	1002	853	944	848	3647

Of the total of 3647 cases, 816 were cases of syphilis, or 22.374 per cent.

*Simple Sores.*—Our diagnosis has often to be made on the eve of a sailor's departure to sea; hence it is possible that

some of these might eventually prove to be the initial manifestation of syphilis. As a rule these simple sores healed up readily, especially with iodoform ointment. Merchant seamen are by no means cleanly in their person, a fact of which we have daily evidence. Hence we have many cases of balanitis, and simple sores are much aggravated by this want of cleanliness.

*Gonorrhœa and Gleet.*—For these the old copaiba mixture still holds its own, and with a few exceptions answers very well. In obstinate cases an injection of sulpho-carbolate of zinc, two grains to the ounce, is ordered as well. Our chief difficulty is to induce patients to abstain from intoxicants until after they are thoroughly cured.

*Bubo.*—These occur very frequently among sailors in conjunction both with simple sores and gonorrhœa. As a rule, after being opened they heal rapidly, especially if this has been done in good time. But in many cases there has been much delay, especially when the disease has been contracted immediately before sailing; in these cases there is much undermining and disorganisation of the parts, and the healing process is much retarded. In these cases, again, we have found iodoform most beneficial, sometimes in the form of powder dusted over the part, or as an ointment (forty grains to the ounce) with or without operative treatment.

*Syphilis.*—The practice of this dispensary affords favourable opportunities for observing the variable periods of incubation, which average from fourteen days to eight weeks. It is true that we cannot place absolute reliance on the statements of our patients, especially as, with the uncleanly habits already noticed, an indurated sore might easily escape notice amidst a mass of smegma. On the other hand, there is the fact that in the case of sailors this incubative period can be determined with more accurate data than in the case of landmen. A seaman discovers that he is infected some weeks after sailing, and therefore some weeks after the possibility of impure sexual intercourse. In a certain number of these cases, the patients being of superior intelligence, we have been able to ascertain the period with great exactness. Primary ulcers are generally situated on the prepuce or in the furrow between the prepuce and the corona glandis, involving frequently both these parts. Induration is generally well marked, and especially in those cases where the disease has been in existence for some weeks without any treatment. In the treatment of syphilis we find it necessary to administer mercury in a very mild form and in small doses, the reckless habits of seamen in exposing themselves to wet and cold, their too frequent intemperance and impaired constitutions, making it imperative to exercise great caution in the administration of this drug. We require them to attend every second day, and supply them with sufficient medicine to last two days. A pill containing two grains of grey powder with three of Dover's powder, made up with confection of roses, is the form we mostly prefer. We also give the biniodide of mercury in mixture, and sometimes mercury by inunction. Our chief difficulty is the short time allowed us by the patients' stay in port, many men proceeding to sea in an unfit state, as will be seen further on. To those who are fit to proceed to sea, but require a continuation of the treatment, we give extra medicines, with every necessary precaution. Our experience here confirms that of most workers in this special line of practice—viz., that syphilitic diseases are most amenable to treatment if taken in proper time, and if the treatment be not interfered with by any untoward circumstances.

The following extracts from our register afford melancholy proofs of the unseaworthy state of many sailors; these being only a few out of many which might be given, and only an infinitesimal proportion of the probable whole number of seamen leaving English ports infected with venereal disease:

March 15th, 1878.—T. D.—. Phimosis, ulcers of prepuce, and indurated glands. To sail next day.

April 23rd.—C. W.—. Indurated ulcer of corona, indurated glands; a very severe case. Going to sea in the morning.

April 27th.—C. W.—. Indurated sore of corona, indurated glands and secondary eruption. Sails on the 4th May.

May 10th.—J. P.—. Large indurated sore of corona, indurated glands. Going to sea in the morning.

May 14th.—J. H.—. Papular eruption on back, loins, arms, forehead, and legs. This man is saturated with syphilis. Going to sea to-morrow.

May 30th.—G. G.—. Ulcer of prepuce, gonorrhœa, sup-

purating bubo. Arrived to-day; unable to work last five days; sent to lock hospital.

Nov. 6th.—J. C.— Syphilitic disease of testicle. Going to sea next day.

Dec. 4th.—J. J.— Orchitis and gonorrhoea. Going to sea next day.

Dec. 18th.—J. Q.— Suppurating bubo; ulcers of prepuce. Just came from sea. Opened bubo.

Dec. 19th.—J. F.— Indurated sore of prepuce; indurated glands; secondary eruption; disease of three months' standing. Going to sea on the 21st inst.

Jan. 13th, 1879.—T. L.— Phimosis; ulcers; suppurating bubo. Going to sea. Seen subsequently on March 20th. A very bad case of syphilis.

July 6th.—J. B.— Paraphimosis; ulcers of prepuce; indurated glands. No room in lock hospital; refused admission to workhouse. Compelled to go to sea.

In some cases we have been able to induce men not to go to sea, but to remain ashore until cured.

As regards the financial success of the dispensary, it will suffice to say that from the very commencement it has paid its way, the receipts from patients enabling us to pay rent, taxes, drug-, dispenser's salary, &c., and to leave a small and we hope increasing balance for honoraria, in accordance with the original rules. The members of the Committee of the Sailors' Home have individually and collectively shown us the greatest kindness and assistance, and the same remark applies to the energetic and indefatigable secretary, Mr. Thomas Hammer.

Liverpool.

## ON TRANSFUSION.

By J. F. LE PAGE, L.R.C.P.E.

CONVINCED that in the conservative practice of the future transfusion will hold a place of no little importance, and will be more and more extensively resorted to, and seeing that the means at present at our disposal for the performance of the operation are not altogether satisfactory, I have devised an apparatus in which there is an endeavour to combine absolute safety with great facility in use.

Of the transfusors which have been at our service that of Dr. Aveling is, perhaps, all things considered, the most serviceable; but it has the disadvantage of requiring very complex manipulation. To put it concisely, each of them requires in its use for the surgeon to be aided by skilled assistance, whilst at the same time there is no safeguard against the injection of a minute quantity of air, however careful and adept the operator may be; an accident which, in all probability, would prove fatal to the patient.

The accompanying illustration shows how these disadvantages are overcome. One hand alone is needed to

operate the transfusor, and the other hand is at liberty to attend to the efferent tube; whilst the attention of the surgeon may be divided between the recipient and the donor of the blood. If any portion of air should at first remain adherent, and, of course, unseen, on the inner surfaces of the tubes, and, during the passage of the blood, be carried along with the stream, their course is with certainty arrested by the glass air receiver, into which they must rise. As to the *modus operandi*: The case contains the apparatus, knife, forceps, and a small bottle, which latter is intended to hold a compound powder composed, say, as follows: Carbonate of soda, ten grains; phosphate of soda, two grains; chloride of sodium, thirty grains. One-fourth of the powder should be dissolved in about two ounces and a half of water at a temperature of 100° F. A few drops of alcohol may be added, and the vessel containing the solution placed in another vessel partly filled with water at a temperature somewhat higher. Then, having attached the receiving and delivering tubes, the two extremities of the

instrument must be placed in the inner vessel with the air chamber downwards. Now press the lever, press the elastic ball, release the lever, release the elastic ball, and, after repeating that process once or twice, turn both taps. It is now ready for use. Raise the patient's arm to the horizontal position, so as to facilitate the transmission of the blood to the heart, and, having inserted both tubes, one into the supplying vein, and the other into the receiving vein—the right median basilic is, perhaps, the best—turn the taps, and, in the same order, press the lever, press the ball, release the lever, release the ball, and so on. Precisely one quarter of an ounce passes out each time. It is expedient, having commenced the transmission of blood, to complete the process without arrest, lest coagula should form. The apparatus is made by Messrs. Arnold and Sons, and their name is quite sufficient guarantee for excellence of workmanship. I must, however, say that my thanks are due to them for so faithfully, so well, and with such precision and care elaborating from my drawings an instrument of some elegance.

A word as to the cases in which transfusion is indicated. My special intention is that of supplying the obstetrician with a safe and facile means of transfusing blood after post-partum hæmorrhage, where the diastaltic system is practically dead, and the heart is dynamically incapable of action in consequence of the absence of fluid to act upon. But transfusion is indicated in many other cases than that of uterine hæmorrhage leading to this condition. For instance, when, after excessive hæmorrhage, the vital fluid is not reproduced, and the nutritive process is so impaired that the persistent anaemia would be the forerunner of phthisis or other grave disease did we not supply red corpuscles to carry oxygen with which to re-establish those functions which are essential factors in the formation of hæmoglobin. And it is certainly indicated in some cases of hæmorrhage from the bursting of an aneurism, or where a main artery has been divided. With its aid life may at least be prolonged, where the stomach and rectum refuse to retain nutriment in the exhaustion from marasmic disease. It may also be resorted to in the asphyxia of new-born infants, the injection being made through the umbilical vein, having previously allowed a little blood to escape from the umbilical artery. For this purpose a small quantity of blood taken from the placenta and defibrinated will answer very well. In chronic as well as in acute anaemia we may transfuse, for where the whole blood is altered by toxic or pathological causes it is manifestly advantageous to improve its quality by the admixture of healthy blood. It may also appear indicated after hæmorrhages from the stomach and intestines, hæmoptysis, and some surgical operations. I would go so far as to suggest, on physiological grounds, its occasional indication in hæmorrhagic fever. In the young who are robust, absorption and nutrition will soon replace the normal quantity of fluid, although for a time it will be inferior in quality to that which was lost, containing less than the due proportion of oxygen carriers, the red corpuscles. In those previously suffering from anaemia, and in the aged whose blood is very slowly reproduced, it appears to me that the operation may, with very great promise, be repeated even more than once, at intervals of a few days. In cases of poisoning, when the nature of the poison is unknown, or when an antidote would not be effective, or in pyohæmia, might not occasionally a life be saved by alternate depletions and injections of pure blood? In epilepsy it has been used with marked success. And, as in puerperal eclampsia we may presume an excess of carbonic acid and a deficiency of oxygen, may we not here also find it of no little service? I should remark that Dr. Schäfer has most conclusively shown that the action on the blood-corpuscles of beef peptones, milk, and some other fluids, when used in lieu of blood, is most injurious.

It has been urged in disparagement of the operation that during transfusion very painful symptoms are experienced, followed, after its performance, by alarming prostration and hæmorrhagic fever. This we may admit to be, in some cases, substantially correct. But what is the cause of all this, but that the vital powers are so stimulated to reassert themselves that the heart and arteries, certainly with intermissions, are making very violent efforts to drive along the small quantity of blood which the system contains? The inference is clear that this most valuable operation has not been so frequently performed as it should have been, and that many invaluable

lives have been lost which might have been saved by the immediate restoration of the failing powers of the heart and nervous system which it most strikingly effects.

Durham.

### CASE OF ACUTE RHEUMATISM,

OCCURRING IN A NEWLY-BORN INFANT, TREATED WITH SALICYLATE OF SODA.

By F. ERNEST POCOCK, M.D.

ON May 25th I was called to see Mrs. A——, who had been ill for two days. I found her suffering from acute rheumatism, with a temperature of 106° 5'. She was pregnant with her second child, and, as far as I could gather, within about a month of her confinement. I ordered twenty grains of salicylate of soda every hour for six doses, and then every two hours. On Tuesday morning, about thirty hours after seeing her for the first time, the rheumatic pains left her entirely, and labour pains came on, resulting in about four hours in the birth of a sturdy male child, who appeared perfectly healthy. The rheumatism returned immediately the child was born, and she could not bear it put to the breast. The milk was dispersed by belladonna, and Mrs. A—— made a fair recovery in about five weeks, but unfortunately with considerable valvular mischief.

The child was a very cross one, and cried very much, which the nurse and the mother attributed to flatulence and want of food. However, dill-water, aniseed, &c., having no effect, I was sent for about twelve hours after the birth. The child was decidedly feverish, with a moist skin and an acid smell about him. I noticed that he appeared to cry more loudly whenever his right arm was moved. On removing the dress, his right shoulder and elbow were found reddened, and on moving either joint he cried lustily. On using the thermometer I found his temperature 103° 5' and his pulse 170, as accurately as I could count it. Under the circumstances, it occurred to me that he might have the rheumatic poison in his blood, and that in fact I had to do with a case of congenital rheumatic fever. As Mrs. A—— was unable to nurse him, and we thus could not give him any medicine per matrem, I determined to administer the salicylate in a direct form. Four grains were given in a little sweetened water every two hours for six doses. The pain then seemed less, and it was given every four hours. However, the restlessness returned, and the temperature was found to have risen to 104°, and it was therefore continued every two hours for four doses more, and then the interval increased to three hours. By this time (about forty hours from birth, or twenty-eight from the commencement of the salicylate) the temperature was reduced to 101° and the pulse to 140. In another twenty-four hours the interval between the doses was increased to four hours, and in another day to six hours or three times a day. When about 180 grains had been taken, and the child was nine or ten days old, the drug was stopped for twenty-four hours, but given again at the end of that time in four-grain doses two or three times a day as occasion required for a fortnight. After this a teaspoonful of cod-liver oil was rubbed into the skin twice a day for three weeks, when the child appeared perfectly well. The temperature had gradually and steadily diminished since it had risen to 104°, which was when the child was thirty hours old, down to the eighth day, when it was normal, and never rose after. Nestle's milk food was given as sustenance, and a few grains of mercury with chalk as occasion required. I was unable to detect anything abnormal about the heart sounds all through.

This is, as far as I know, a unique case, and I trust it will be of interest to the profession. It seems to show that the salicylate does not deserve quite all the hard things that have been said and written about it; and that even in the case of a newly-born infant it may be pushed almost to an extreme without producing the head symptoms which have so often been laid to its charge. May not these latter, in many reported cases, have been due to the rheumatic blood circulating through the brain, and not to the drug?

St. Mark's-road, North Kensington.

OF

### HOSPITAL PRACTICE, BRITISH AND FOREIGN.

*Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.*—MORGAGNI *De Sed. et Caus. Morb.* lib. iv. Proœmium.

#### UNIVERSITY COLLEGE HOSPITAL.

TWO CASES OF INCREASED EYEBALL TENSION; ONE REDUCED BY ESERINE, THE OTHER BY ATROPINE.

(Under the care of Mr. TWEEDY.)

AMONG the cases lately presenting themselves in Mr. Tweedy's clinique were two of considerable therapeutical and pathological interest. In both the tension of the left eye was greatly increased, though from different causes. In one the tension was reduced to normal by means of a pupil-contractor, eserine; while in the other a similar result was produced by a pupil-dilator, atropine. In the first the disease was intermittent glaucoma; in the second, recurrent iritis. The interest of the cases is increased rather than diminished by the fact that such examples are by no means infrequent, and their gravity by the fact that a mistaken choice might be disastrous. To employ atropine in glaucoma and eserine in iritis would, besides aggravating the existing symptoms, in all probability induce irreparable mischief. Mr. Tweedy alleged that it had become too much the fashion to regard increased tension of the globe as always identical with glaucoma. This is as irrational as it would be to regard ascites as always and only indicative of cirrhosis of the liver. The second of these cases showed that there may be a high degree of hardness of the eyeball, and yet an absence of glaucoma. In glaucoma the increased tension usually supervenes on changes affecting the drainage apparatus of the anterior segment of the globe, checking elimination, whereas the increased tension occurring in iritis and allied conditions primarily and chiefly depends on engorgement of the vascular tunics of the interior of the eyeball and on the formation and accumulation of inflammatory products. Eserine and other myotics could not, it was stated, be looked upon as the rivals of iridectomy or sclerotomy in glaucoma, they were rather adjuvants, and at most alternative in cases where operation was not imperative or was otherwise impracticable. On the other hand, as glaucoma is a cumulative condition the judicious employment of myotics might correct the vice on which the malady essentially depends, and thus ward off an actual outbreak.

For the following notes we are indebted to Mr. F. Knight, ophthalmic assistant.

CASE 1. *Intermittent Glaucoma; increased Tension rapidly reduced by Eserine.*—Maria B——, aged fifty-five. On August 21st the patient was seized with severe pain across the top of the head, in the forehead, and left eye. For a week this pain was constant and prevented sleep. On August 28th a blister was applied behind the left ear, and this seemed to relieve the pain considerably. After a day or two the pain returned, and up till Sept. 11th the pain recurred nearly every day, each attack lasting eight or ten hours. During these attacks the patient could not bear any light and had to have the room darkened. Objects looked foggy. On September 11th she came to the hospital for dimness of the left eye and neuralgia. The left pupil was slightly larger than the right, the tension normal and equal; V =  $\frac{2}{3}$  in the right eye, and  $\frac{3}{4}$  in the left. The left optic papilla was "shallowed." From the history rather than from the physical signs a diagnosis of intermittent glaucoma was made. Quinine mixture was ordered. On September 17th the patient was seized with an attack of pain, and when seen on the following day the tension was increased to T + 2, the vision had greatly diminished, the media were hazy, and there was visible pulsation of the central artery of the retina. A drop of a solution of sulphate of eserine (two grains to the ounce) was applied to the conjunctiva of the left eye, and in half an hour the tension had sunk to normal, the pain had ceased, and the sight had improved. Eserine was ordered to be

applied twice a day. No recurrence of pain, increased tension, or obscuration having occurred in the interim, a solution of nitrate of pilocarpine (two grains to the ounce) was, on October 5th, substituted for the eserine as being less costly, and in some cases as effectual. On the 9th the eye was not so well, the tension was increased, the pupil semi-dilated, and the sight was "misty" again. Eserine was applied once more, and in half an hour the tension was normal, the pain gone, and the sight clearer. Since then eserine has been used twice a day, and the sight and general condition of the eye have steadily improved.

**CASE 2. Recurrent Iritis; Increased Tension (T + 2); Reduced by Atropine.**—S. C., aged forty, a tailor, was seized with violent pain in the right eye on waking on the morning of Oct. 24th, 1881. The pain continued till Nov. 7th, when he applied at the hospital. He then had marked kerato-iritis with many posterior synechiæ. The pharmacopœial solution of atropine, applied many times at short intervals, failed to dilate the pupil. Leeches were applied, a mercurial and colocynth purge was given, and atropine was instilled every two hours. The pain speedily subsided, and in a few days the eye was apparently recovered. The left eye was then attacked, but soon got well. In the following January episcleritis appeared in the right eye, and continued some weeks. On February 23rd, however, the eyes were quite well; the acuteness of vision was normal. On March 9th there was another recurrence of iritis, with posterior synechiæ in the left eye, but this attack responded gradually to treatment, and on May 1st the patient resumed work, and continued to work with comfort till Oct. 14th. On the morning of this day the left eye was again attacked with recurrent iritis of a severe type. The patient applied leeches and poppy fomentations, but did not attend at the hospital till the 17th, when he had an extreme degree of kerato-iritis; the aqueous was turbid, the pupil greatly contracted and blocked with lymph, which extended over the whole surface of the iris and covered it. The tension was increased to T + 2. Atropine was applied at short intervals, and one grain of calomel and a quarter of a grain of opium were given three times a day. On the 19th the pain was less, the tension somewhat diminished, and the pupil was semi-dilated, exposing a narrow space between the edge of the iris and the circular mass of lymph in the pupillary area. Three days later, the same treatment having been continued, the pain had ceased; the pupil was rather larger, the cornea bright, the lymph gone from the pupil, and the tension was if anything subnormal, from inflammatory softening.

### LEEDS PUBLIC DISPENSARY.

CASE OF ANEURISM OF BASILAR ARTERY; RUPTURE;  
DEATH; NECROPSY; REMARKS.

(Under the care of Mr. C. J. WRIGHT.)

FOR the notes of the following case we are indebted to Dr. Hudson.

William —, aged sixteen, currier, was found in the street in a fit, at 4 P.M., March 12th, 1882. He was conveyed to an inn and given some whisky, after which he attempted to walk home. After going about forty yards in a semi-stupefied condition, he fell down insensible, not convulsed, and was taken home by a policeman, vomiting profusely on the way. At 7 P.M. he was seen by Dr. Hudson. He was then lying on his back, his face pallid and covered with perspiration, as also the rest of the body; pupils dilated, equal, not responding to light, no apparent loss of muscular power, limbs flaccid. He could not be aroused by loud speaking; pulse 79, full, compressible; respiration 26; temperature 100.4°. There was no paresis of the sphincters, nor any loss of blood from the ears or mouth. The nostrils were partly filled with clotted blood, and a trace of the same was on the upper lip. There was no evidence of fractured skull or other injury. At the bed-side was some vomit slightly and equally mixed with dark blood. There was no injury of a former date, nor history of any illness to be elicited, neither was there suspicion of foul play. The head was shaved and an ice cap was applied. The vomiting having ceased, six grains of calomel were placed on the tongue. At 10.30 P.M. he was seen by Mr. Wright. He could now be roused, and answered "Yes" to a question about pain, putting his right hand to the frontal region and keeping it

there. The pupils were normal and acted well; there was no paralysis, no return of vomiting, and the bowels had acted freely. Pulse 80, dirotous; respiration 24; temperature normal. Perfect quiet was enjoined, soda-water and milk were given, and the ice was continued.—13th: More conscious; complains of great pain in the frontal region with intolerance of light, and of nausea. He remembers feeling "dizzy" and falling, nothing further; urine normal. Ordered an effervescing draught, with ten grains of bromide of potassium every three hours.—14th: Has not slept owing to the frontal cephalalgia; looks very pallid, is warm, and has not vomited again. No blood in nostrils; no melæna. Respiration and temperature normal; pulse 80, firmer. Ordered two ounces of compound senna mixture, and a blister to nape of neck.—16th: Has slept two hours, and had less pain; bowels very confined; passes water freely, and has perfect control over the emunctories. To continue with draught and have a powder with six grains of calomel and a drachm of compound jalap powder at bedtime.—18th: The frontal pain alone complained of, and which entirely prevents sleep; no vomiting. Temperature normal. To have nightly a draught of three grains of chloral hydrate, with twelve grains of bromide of potassium.—23rd: Still intense frontal pain. A seton inserted in nape of neck. To have seven grains of iodide of potassium three times a day, and mercurial ointment applied to the arm.

April 4th: The pain continuing, though not so severe as before, a seton was put in the nape of the neck, and the mixture increased to twelve grains of iodide of potassium three times a day. The draught at bedtime was continued, as he only slept after taking it.—12th: Has less pain, eats well, and sits up in bed daily.—14th: No pain for two days. The ointment to be discontinued, and the seton removed.—20th: Was out of bed two hours.—24th: Reported by his mother to have had a "fit" at midnight, not being convulsed but falling suddenly on the floor. He remained unconscious forty-five minutes, and continued "dazed" for hours afterwards. He vomited shortly after the "fit." He still seems stupid, and complains of great pain over the left orbit, whereas previously it was referred to the whole frontal region. Bowels unmoved for two days. To continue mixture and draught, and two compound colocynth pills at bedtime.

May 1st: Has no pain, and been up for the first time since the "fit."—11th: Having had no pain for twelve days the iodide was reduced to two grains thrice daily, and the draught discontinued.—12th: Attended at the dispensary, walking well, and only looking pallid. Ordered to Ilkley. 13th: Went to the theatre, and while down in the vestibule between the acts had a "fit," at 10 P.M.; was taken to the General Infirmary and expired immediately after admission, at 10.30 P.M.

**Necropsy, forty-two hours after death.**—A large quantity of clotted and semi-fluid blood covered the whole surface of the brain, especially the base, extending over and down below the medulla oblongata and through the transverse fissure into the lateral ventricles. An aneurism about the size of a small bean was found at the junction of the basilar with the left posterior cerebral artery, which had given way in its lower wall, the opening being about the size of a large pin's head. The coats of the aneurism were extremely thin, especially around the ruptured point. There were no signs of any former fracture of the skull. Other organs healthy.

**Remarks by Mr. WRIGHT.**—Although the cases of cerebral aneurism upon record are somewhat limited, they are probably in reality more common than is supposed, owing to the real causes of some hæmorrhages over the brain being either overlooked or never ascertained; such cases being either not examined after death, or simply set down as under the head of "apoplexy." The basilar artery appears to be the most usual seat for the development of a cerebral aneurism, which probably can seldom, if ever, be diagnosed with certainty during life. In the above case the main symptoms were the epileptiform attacks, the fixed and persistent pain in the forehead, giddiness, with consequent sleeplessness, and intolerance of light. The patient, aged sixteen, was young for disease of this character. Of sixty cases of cerebral aneurism mentioned by Dr. Tanner,<sup>1</sup> including fifty-two cases collected by Dr. Brinton,<sup>2</sup> the average age was forty-one, the youngest patient being fourteen, the oldest sixty-five. It may be a question how far

<sup>1</sup> Practice of Medicine, sixth edition, vol. II., p. 455.

<sup>2</sup> Transactions of the Pathological Society, vol. III., p. 47. 1852.

the first attack, which took place in the street, and the second during his illness, may have been due to some oozing from the aneurismal sac. No trace or proof of this, however, was found after death. It is worthy of note that the fatal seizure due to the rupture took place, not during the excitement of a sensational play at the theatre, but between the acts—i.e., during physical exertion subsequent to the mental effort.

## Medical Societies.

### PATHOLOGICAL SOCIETY OF LONDON.

*Congenital Malformation of Heart.*—*Paraplegia.*—*Disseminated Sarcoma.*—*Xanthoma Tuberosum.*—*Pigmentation of Uterus.*—*Empyema from Foreign Body.*—*Malformation of a Lamb.*

THE ordinary meeting of this Society was held on Tuesday last, Dr. S. Wilks, in the chair. The report of the committee appointed at the last meeting to examine Dr. Norman Moore's specimen of deformity of the heart was read to the Society. The specimens shown by Dr. Kesteven and Dr. Hadden were referred to the Morbid Growths Committee. Dr. Malcolm Morris read a very complete account of a remarkable case of skin disease, his designation of which—*xanthoma tuberosum*—was not accepted by the other dermatologists present, who, however, did not suggest any other name for it. The case was referred to the committee which last year reported upon *xanthelasma*.

Dr. P'ye-Smith read the report of the committee appointed to examine Dr. Norman Moore's specimen of narrowing of the left ventricle below the aortic valves. The committee could not decide whether it was congenital or acquired, but were of opinion that the fibrous ring was of later date than the formation of the aortic opening and septum ventriculorum, and of earlier origin than the aortic aneurism, and therefore they referred it to the later period of intra-uterine life.

Dr. KESTEVEN related a case of Paraplegia, caused by Traumatic Hæmatoma, in the Dorsal Region. In this case there had been some pre-existent disease, which had caused the spontaneous removal of the body of the seventh dorsal vertebra. About three months before death occurred the patient had received a blow on the back, which had caused some displacement at the diseased part and rupture of some bloodvessels, thus giving rise to an effusion of blood into the spinal canal, and consequent pressure on the cord. Some of the blood had also escaped anteriorly, forming a hard tumour in the posterior mediastinum, which had pushed forward the sympathetic ganglia and caused destruction of the rami communicantes of the seventh ganglion on each side. The heads of the seventh and eighth ribs on each side were also diseased. The narrator of the case gave an account of the symptoms produced, and pointed out the effects produced by the pressure on the cord, and by the damage caused to the sympathetic nervous system.—Mr. ROGER WILLIAMS said the case was interesting as an example of cure of spinal caries without suppuration. It showed, too, that paralysis was produced by the tumour pressing upon the spinal cord. He thought it might be also an example of what Sir James Paget had called "residual abscess."—Dr. HORROCKS observed that this was the first case on record in which ankle clonus had not been associated with degeneration of the lateral columns of the cord; although clonus had been present for a few seconds after a fit from temporary exhaustion of the lateral columns.—Mr. BUTLIN asked if the blood-clot had been examined microscopically, as it looked like a blood-cyst or hæmorrhagic sarcoma. There was no trace of suppuration, and the history pointed rather to a tumour than to hæmorrhage.—Dr. KESTEVEN replied that it had not been examined microscopically.—Dr. WILKS supposed Dr. Horrocks did not mean that the excess of spinal reflexes was directly produced by lateral sclerosis. He thought it was due to excitation of the grey nervous matter within the degenerated cord.

Dr. HADDEN described a case of Disseminated Sarcoma. The patient was a gentleman, aged thirty-eight, in St. Thomas's Home. Shortly before admission he had been

operated on for fistula in ano. On admission, he was dull and drowsy; this increased; then oedema of the legs came on; the pulse became very small and frequent. Temperature reached only 101.2°. No optic neuritis, nor evidence of organic disease during life. He died comatose. Post-mortem: The pericardium on each surface was studded with small new growths; similar growths were seen in the muscular substance of the heart, parietal layer of pleura, both surfaces of diaphragm, omentum, mesentery, liver, and spleen. The right kidney was remarkable, the capsule was studded with numerous white masses of calcareous matter. Several small bodies like tubercles were seen on the arachnoid, which were found to be only thickenings of the membrane; no glands enlarged. The tumours were round-celled sarcomata. In the heart the cells were round; matrix amorphous, in some places alveolar. In the liver the growth was interlobular. Beneath the capsule of the right kidney was an extensive infiltration of round cells, which sank down between the tubules. The case during life was thought likely to be acute tuberculosis, and was also very interesting, as the symptoms were acute, lasting only a fortnight.—Dr. NORMAN MOORE asked if the new growth on the kidney was the same in character as that in the heart; and whether Dr. Hadden was sure the growths were sarcomatous. The indurations on the kidney were like those common on the liver. He thought that in the heart sarcomata were nearly invariably pigmented.—Mr. BUTLIN had examined these specimens carefully, and was not prepared to affirm that the growths were sarcoma growths if this would be in opposition to the general characters of the disease. It was extremely difficult to distinguish such round-celled sarcomata from tubercular deposits or other round-celled formations.—Dr. BEDFORD FENWICK remarked on the paroxysmal character of the pain associated with new growths in the heart.—Dr. HADDEN replied that the growth in the right kidney in the main resembled that elsewhere. He had never seen any growth quite like it, and he thought it unique. He did not know whether there was paroxysmal pain in the region of the heart.

Mr. MALCOLM MORRIS showed a living specimen of a very rare skin disease which he called *Xanthoma Tuberosum*. The patient was a married man, aged forty-eight, who was suffering from saccharine diabetes. There was no history of syphilis or rheumatism; no jaundice or evidence of disease of the liver. He complained of sleeping badly, and of dimness of sight with occasional mists before his eyes. There was distinct anaesthesia of the soles. Heart weak; reflexes normal. The eruption appeared suddenly, first on the outer side of the thigh, then spreading to the trunk, to between the fingers, and on the mucous membrane of the mouth. It consisted of small rounded firm pink tubercles, with depressed centres which had more of a fawn-colour in the centre. Many of the papules had disappeared since the case first came under his care. With the patient's consent he removed one of the growths and examined it microscopically. This showed small nodules in the corium, with a delicate fibrous intercellular matrix; towards the centre the fibrous tissue became more compact and firm. The superficial epithelial cells were normal. There was no connexion with any glandular structures, and the older papules contained no blood-vessels. In one place he found a collection of round cells about a vessel, and he suggested whether this might not be the real origin of the growths—the tissue ultimately contracting and so causing degeneration of the cells. This case differed from those of *xanthelasma* in many respects, chiefly in its association with diabetes and not with jaundice; the sudden onset of the rash, and its rather rapid disappearance, and in the fact that the eyelids were not implicated. But on the other hand it closely resembled two cases, one of which had been recorded by Drs. Gull and Addison, the other by Dr. Bristowe. The three cases were all in men; they all had diabetes, they all affected the same locality and avoided the same parts; in all the rash appeared suddenly, and gradually, but rather rapidly, disappeared. To these exceedingly rare cases the name of *xanthoma tuberosum* had been applied.—Mr. MORRANT BAKER said the case was of great rarity, but it differed so much from *xanthelasma* that he doubted whether it should have that name at all.—Dr. DUCKWORTH said that the case did not resemble *xanthelasma* and ought not to be called by that name. Its actual appearance did not justify the use of the term applied to it.—Dr. RADCLIFFE CROCKER said in *xanthoma* the nodules were always soft and yellow, but these were firm and not yellow. The rapid appearance and disappearance of the rash quite separated it from true

**xanthoma.** In xanthoma there were, also, stellate fat cells and oil globules.—Dr. MORRIS said the rash was chamois-leather coloured in the centre and pink in the centre. There was an absence of the oil globules in ordinary xanthelasma; microscopically it was more like keloid or fibroma, but it was exactly like the cases described early by Drs. Addison and Gull as xanthoma tuberosum. The case was referred to the Committee appointed last year to investigate xanthelasma.—Dr. MORRISON compared this rash with the eruption common in gout, and said it was also similar to molluscum. He thought in all such cases the parts affected first were the hair-follicles and sebaceous glands.

Dr. ROBERT BARNES showed a specimen of Pigmentation of the Cervix Uteri. It consisted of the vaginal portion of a uterus affected with hypertrophy, and which projected from the vulva. It was pigmented on the surface. The patient was a Hindoo. The parts not exposed were of the normal rose colour. Dr. Ewart had examined the part microscopically, and found the pigmented surface to have the leading characteristics of healthy skin; the horny layer was thin; rete Malpighii well furnished with closely-packed cells, like those of the skin; the deep vertical cells were deeply pigmented; papillæ projected forwards into the epithelium, and contained vessels of new formation. In the unpigmented part the corium was absent, the rete abutting upon the firm muscular tissue of the uterus. The pigment consisted of fine granules, and was present in the nuclei of the cells. There was thus evidence of a further change than one of dying of the exposed surface of mucous membranes. It was new to him, but probably familiar to practitioners in India.—Dr. WILKS said that pigmentation was a very difficult subject, for in some cases it was due to local causes, and in others to deep constitutional changes, as in Addison's disease. Professor Laycock thought that the pigmentation of the face was always associated with disease of the genital organs.

Dr. NORMAN MOORE read a paper on Lung with Impacted Foreign Body. The right lung of a child, aged twelve, who died of typhoid fever. The lung is partly collapsed, and in its lowest lobe are several reddened patches. In one of these, near the pleural surface, was fixed a spicule of bone three-quarters of an inch long. The spicule, which looks like the neural spine of a fish vertebra, had one end in a minute bronchus, the wall of which it had penetrated. Four years ago the child was suddenly seized with pleurisy. It was tapped in St. Bartholomew's Hospital, pus was let out, and as the wound continued to discharge a drainage-tube was put in. The child attended with this as an out-patient, and at length the wound was closed. The scar was distinct. The lung was firmly adherent to the chest-wall. The spicule of bone passing deep into the lung probably set up pneumonia, which was followed by the empyema four years ago. The empyema was emptied, and the bone remained, a very exceptional circumstance. The typhoid fever, of which the girl died, was remarkable in the large extent of intestine affected, and in the fact that the middle part of the vermiform appendix was externally tumid and internally ulcerated all round. Perforation of the vermiform appendix had occasionally been a cause of death in typhoid fever, and had been thought a condition preceding the fever. In this case, and in another post-mortem which he had lately made, the ulceration of the vermiform appendix was clearly one of the results of the typhoid fever. A further point of interest was that in the middle of the epiglottis there was a small ulcer.—Dr. GOODHART said that foreign bodies more commonly caused lung disease than was generally suspected; he had made two autopsies quite close together of cases of obscure lung disease, in each of which he discovered the cause of the mischief in a foreign body.—Dr. MACLAGAN said that in cases of foreign body in the lung there was fetid expectoration of a peculiar odour. Dr. Begbie had particularly pointed this out, and had been able to diagnose the source of a troublesome cough and expectoration by this means; he also found that turpentine given internally removed the fetor, and rendered the patient more comfortable.—Dr. SHARKEY said that it was not necessary to suppose that the foreign body had actually passed through the lung, and so caused the pleurisy, for in cases of obstruction of a bronchus by an anæmism, lobular pneumonia and pleurisy were often met with. He had under his care a patient with a tooth in a bronchus, causing partial obstruction, and he got an attack of pleurisy, although the tooth was still in the bronchus.

Mr. EVE showed a specimen of Malformation of a Lamb. All the parts developed from the first visceral arch were

absent on one side; the superior and inferior maxillary bones and palate bones were absent; the temporal bone was dwarfed, and there was no trace of the ossicles of the ear. The brain and cranial nerves were normal, except that the fifth and ninth nerves were smaller on the right (the deformed) side. He had not been able to examine the arteries. He could not find any similar case, although absence of the lower jaw was tolerably common in lambs. Possibly, the cause of the deformity was some vascular lesion, as thrombosis of the internal maxillary artery.

The following card-specimens were shown:—Congenital Malformation of Skull, by Mr. F. Treves; Double Hydro-salpinx, by Dr. Norman Moore.

## CAMBRIDGE MEDICAL SOCIETY.

At the meeting on Oct. 6th, 1882, Professor Humphry, President, in the chair,

Mr. WHERRY related a case of Complete Inversion of the Uterus. The patient was a woman who had been delivered two days previously of a healthy male child, which was born rather suddenly and with a short thick cord. She was given twenty minims of liquid extract of ergot after delivery, and shortly after this had a pain, and there was protruded from the vagina what at first appeared like the head of another child, but which proved to be the inverted uterus, with the placenta adherent. There was not much hæmorrhage. The medical attendant detached the placenta and endeavoured to replace the uterus by his hand, but he was obliged to desist, owing to the great softness of the uterine walls and the collapsed condition of the patient. Two days later, when called in, Mr. Wherry found the uterus completely inverted. Ether was administered, but it was quite impossible, owing to the doughy softness of the fundus, to replace the uterus with the unaided hand. Accordingly a large rubber drainage-tube was inflated to about the size of an egg at one end and ligatured. The band, in the form of a cone, was passed into the vagina, and the finger tips, pressed against this air pad, were in no danger of lacerating the walls of the uterus. Half an hour's pressure, first with one hand and then with the other, against the most prominent part of the fundus, at length reduced the uterus, leaving the dilated tube in the cavity. The string was then cut and the collapsed tube withdrawn. The replacement was not by a jerk, but gradual, and to be compared to the relief of a paraphimosis; it was evidently effected by squeezing fluid out of the oedematous tissues of the uterus. The patient, after three days of fever and pain in the body, made an excellent recovery.—Dr. INGLE said that complete inversion of the uterus must be a rare occurrence if the figures given in some textbooks were correct. Braun states that of 150,000 births in the clinics respectively under the charge of Spæth and himself, not a single complete inversion had come under their notice. There was one case in 190,000 confinements at the Rotunda; but much doubt has been thrown on these statements by later writers. He had not seen a case of complete inversion, but remembered one of partial, in which the patient died very quickly from hæmorrhage. Might not such an accident arise from a mal-condition of the walls of the uterus brought on by constitutional disease; by previous imperfect involution; or from irregular contractions; the normal rhythmical movements of the muscular coat being interrupted from either of the above causes? Would not restoration be better effected by the free use of chloroform before an attempt at replacement? It had been shown by Dr. Hewitt how more or less inversion may occur days after labour from incautious exertion. Is it not likely that partial inversion takes place much oftener than is supposed, but is altogether overlooked, leading to grave subsequent interruptions of the monthly health?

Mr. T. LUCAS (Cambridge) produced a specimen of Membranous Cystitis from the bladder of a woman he had attended for this condition. The patient was twenty-eight, and was delivered of her third child in 1881. She had phlegmania dolens after the birth of her second child. On the ninth day after her last confinement she had pain over the hypogastric region and retention of urine. In a few days she had feverish symptoms and a temperature of 103°, pain in the left groin, followed by swelling of the left thigh and leg. The use of the catheter was required for twelve days, after which time the leg was well. The urine contained mucus and albumen. Ten days later there was complete and sudden reten-

tion of urine, and on passing the catheter an obstruction was met with which proved to be a piece of membrane blocking the urethra. This was withdrawn in pieces, and then a quantity of ropy urine escaped through the catheter. A few days later a piece of membrane about six inches by four was removed, and subsequently another piece, ten by twelve inches, came away. Ten days later the woman had entirely recovered. The membrane consisted of a fibrillated network, in the meshes of which were enclosed leucocytes, granular matter, and crystals of phosphate of lime, and seemed to be a cast of the mucous surface of the bladder.—Dr. HUMPHRY said he had, in the case of a young woman, dilated the urethra with his finger and removed a large amount of mucus membrane covered with phosphatic deposit; and observed that the mucous membrane of the bladder had hardly any secretion and very little glandular substance. In cases where the whole mucous membrane sloughed off it seemed due to a process called by Leuchars necrosis of the membrane.

Dr. W. A. SMITH (Newport) related a case of Lateral Sclerosis. The patient, a man, aged forty-four, eighteen years previously had sprained his back by lifting a heavy weight, and had for the last two years been getting more feeble and stiff in his back, and had pains in his legs. He was removed to St. Walden Hospital, and while there the chief symptoms were general rigidity of back and legs, excessive knee-jerk and ankle clonus, slightly impaired sensation, especially in left leg, and considerable wasting, also deep-seated tenderness at lower part of spine on pressure, and pain extending to the groin. There was also a general shaky condition of head and lips, and fibrillary twitchings and stiffness about muscles of the neck. He was treated with iodide of potassium, blisters, and actual canterbury. Dr. Smith considered the case one of lateral sclerosis, with very slight, if any, disease in the posterior columns, and that the stiffness of the muscles of the head and neck might possibly point to some patches of sclerosis high up in the cord. He discarded the notion that there might be any deep-seated caries, but thought these pains might be due to pachymeningitis of the cord. This, too, would satisfactorily explain the lateral sclerosis, because primary sclerosis is very rare, the disorganisation usually following a focal lesion as a focal myelitis.—Dr. BRADBURY mentioned a case he had treated in hospital, and which had rapidly mended under the use of iodide of iron and the battery, after the failure of other remedies, and another case in which ankle clonus and knee-jerk had existed and in which iodide of potassium had failed, but which had, after two months, nearly recovered under the use of syrup of the iodide of iron and quinine.—Dr. PAGET referred to a case under his care where spinal disease occurred in a man accustomed to violent exercise in cricket, skating, &c.

Dr. BRADBURY narrated a case of Cerebellar Tumour. The patient was twenty-two years of age, had never had syphilis, and there was no history of injury or fits. He had been subject for years to neuralgia in face and forehead, and for a month, before coming under Dr. Bradbury's care, to neuralgic pain on the top of the head and the occipital region. Sleep was disturbed, and the pain had exacerbations every few minutes, always increased at night. Had vomited at first, but that abated. There was an expression of suffering in the face (in May), pain in occipital region, but no signs of disease in the thoracic or abdominal organs, and the optic discs were normal. In June he had had considerable relief from pain and had taken belladonna and quinine, and afterwards iodide of potassium. During the next month he had occasional sickness and pain varied in amount. In July he lost control over his rectum, but not over the bladder. He was unable to walk without help, but when assisted took short hesitating strides with some tremor of legs. Gait unaltered when eyes shut; has had no tendency to bear to one side more than the other in walking. Sensation unaffected. Patellar reflex slightly exaggerated. No ankle clonus. In August there was no vomiting or diarrhoea, but a good deal of headache, though there was progressive weakness and emaciation. On September 9th he died rather suddenly, after having got steadily weaker. The pain had diminished and he had been getting drowsy, and had lately lost the control of his sphincters. The autopsy revealed a tumour in the right hemisphere of the cerebellum, as large as a hazel nut, consisting of a white cheesy mass of irregular shape, surrounded by softened cerebellar structure of a reddish colour with a few hæmorrhagic spots. The rest of the lobe was softened and altered. In the left lung was a small cavity

at the apex, surrounded by caseous tubercles, and there were milary tubercles scattered in the lower lobes of both lungs. Dr. Bradbury remarked that in this case two of the symptoms of an intracranial growth were present at an early stage—viz., vomiting and cephalalgia; another symptom, double optic neuritis, was absent throughout, as sometimes happens in cases of even large intracranial tumours. As there was no optic neuritis or atrophy, so the sight was not affected. The diagnosis of cerebellar tumour was based on the seat of pain, which was chiefly occipital, and the peculiar gait of the patient, which was like that of a drunken man—a swaying of the trunk during progression from front to back and from side to side. This has been called the "cerebellar reel." Vertigo was not a prominent symptom. During the latter part of his illness the patient lay in a peculiar apathetic condition, but answered questions on being roused. There was no complaint of stiffness about the back of the neck. The patellar tendon-reflex was slightly exaggerated. The presence of tubercles in the lungs showed the cerebellar tumour to be of a tuberculous nature.

## MIDLAND MEDICAL SOCIETY.

THE first ordinary meeting of this Society was held in the Birmingham Medical Institute on October 25th, Dr. Malins, president, in the chair.

Mr. FURNEAUX JORDAN exhibited a specimen of a Suppurating Node, situated on the upper portion of the diaphysis of the tibia. The child was the subject of inherited syphilis, and its general condition was such as to necessitate removal of the affected limb above the condyles. The subsequent recovery was rapid.—Mr. CHAVASSE thought that the bone disease of inherited syphilis originated in the medulla of the diaphysis, as suggested by Waldeyer, and was not an osteocondritis commencing in the cartilage.

Dr. MALINS showed a new form of Uterine Sound of ingenious construction.

Mr. CHAVASSE exhibited a specimen extracted by lateral lithotomy from the bladder of a man forty-seven years of age. It consisted of three inches of solid indiarubber tubing thickly coated with phosphates. The patient had introduced the tubing to relieve himself of scalding during micturition.

Mr. E. L. FREER showed a portion of the Cranial Vertex, about two inches square, devoid both of aponeurosis and dura mater, which had been blown off a boy's head by the bursting of a small pistol. The weapon contained neither bullet nor foreign body. Death was instantaneous.

Mr. FURNEAUX JORDAN gave the details of three cases of Gunshot Injury to the head, in which recovery took place with retention of the bullets. The first was that of a man who shot a woman through the ear, and afterwards himself, with a fatal result. The bullet entered the woman's external auditory meatus, and passed into the petrous portion of the temporal bone. With difficulty a portion of the bullet was extracted by one of the three surgeons who met in consultation, but it was deemed advisable to make no attempt to interfere with the remaining part. The patient made a perfect recovery. The second case was that of a middle-aged clergyman and magistrate, seen in association with Mr. Walker of Upper Gornal, who was deliberately fired at three times. The first bullet entered behind and above the right mastoid process and penetrated to the interior of the cranial cavity, as evidenced by an escape of cerebral matter through the wound. The second bullet entered the mouth, passing upwards and perforating the hard palate. The third bullet entered the side of the neck, and probably lodged in the body of one of the cervical vertebrae. On receipt of the injury the patient did not fall, although a certain amount of shock resulted. When examined by Mr. Jordan the wounds were dry and covered with blood-clot, so no attempt was made to dislodge the bullets. With care and quietude a complete recovery resulted, and now, after three years, a hard substance can be felt along the floor of the right orbit. This is considered to be the second bullet, which has worked its way into the orbital cavity, where it gives rise to no inconvenience. The third case was that of a gentleman who was seen in consultation two days after an attempt had been made at suicide. The pistol had been pointed just above the right zygomatic arch, and the bullet had probably passed towards, and fractured, the roof of the right orbit. The brain matter was found

outside the wound. There was complete unconsciousness and an enormous sanguineous extravasation around the orbit. The aperture of the bullet was small and covered with a dry blood-clot. Expectant treatment was adopted; consciousness gradually returned. The extravasation subsided, and ultimately recovery took place. Mr. Jordan agreed with the general rule that no attempt should be made to extract bullets which had perforated any of the great cavities of the body unless they can be easily and certainly reached, the retention of the bullets giving the patient a far better chance of life than that afforded by strong or prolonged efforts to extract them. To trephine in such cranial injuries was held to be a dangerous expedient. If ever needed it should be only with full Listerian precautions. If any foreign body is driven into the wound the prognosis is rendered more grave, but pieces of bone were not regarded as such a bad complication as were portions of clothing.—In the discussion which followed, Mr. GREENE gave an account of an attempted suicide in which the bullet was found quite flattened out, lying in contact with the parietal bone.—Mr. EALES narrated the case of a man, aged sixty, who, in the dissecting-room at Queen's College, was found to have a bullet encysted in the mastoid process, and impinging upon the lateral sinus. On inquiry it was found that the man was an old soldier who had served in the Crimea and also in the Indian Mutiny. The wound had been received many years before death.—Mr. PRIESTLEY SMITH, who had had charge of a hospital in the Franco-German War, and many hundred cases of bullet wounds, did not see or hear of any instance recurring in which the cavity of the skull had been opened. Such patients generally died before they could be sent back from the front.—Mr. Freer, Mr. Bennett May, Mr. Jordan Lloyd, and Mr. Harman also made remarks upon the paper.

Dr. SAUNDBY read a paper on the Treatment of Epilepsy, in which the following points were insisted on:—1st. The value of combining the bromides of potassium, sodium, and ammonium, as recommended by Professor Brown-Séquard. 2nd. The advantage of adding tincture of digitalis and sometimes theine to the mixture to counteract the depressing influence of the bromides. 3rd. The utility of zinc as an adjuvant in the treatment. 4th. The successful use of borax in some cases of obstinate epilepsy, of which two illustrative cases were given. 5th. The value of theine or caffeine and nitro-glycerine in the treatment of epileptic vertigo.—In the discussion which followed the paper, Mr. R. Smith, Dr. John Greene, Mr. J. H. Palmer, Mr. Lloyd, Dr. Robinson, Mr. Eales, and Mr. Chavasse took part.

## Reviews and Notices of Books.

*Clinical Lectures on Diseases of the Heart and Aorta.* By GEORGE WILLIAM BALFOUR, M.D. Second Edition. London: J. and A. Churchill, 1882.—Those who made the acquaintance of this work on its first appearance will not be surprised at the publication of a second edition, for few works of its class have been so favourably received. The great merit of the book was its thoroughness and the ability with which its author grappled with the problems of cardiac physiology in their application to the results of clinical experience. He did this in a manner which showed how deeply he had pondered the subject, and his book revealed to many a large field of observation and inference previously too much neglected. It speaks well for the pursuit of scientific medicine that we should have occasion to welcome a second edition of a work of this kind within so short a time. Amongst the contributions made by the author to therapeutics is his insistence upon the value of digitalis in aortic regurgitation, and he points out that there is no fear of any cumulative effect if the dose given be small, whilst with a continued flow of urine no ill results may be anticipated. He far prefers arsenic to iron in combination with digitalis. Another point upon which the author insists is that the presystolic, or rather the auricular systolic, murmur is the only bruit really distinctive of disease of the mitral valve. As a means of timing the murmur he prefers the carotid pulse; and his explanation of the characters of the bruit is exact and sufficient. He

notes also its tendency to disappear, and also describes other murmurs—e.g., diastolic and a systolic in the pulmonary area—as occasionally produced by mitral stenosis. The significance of the irregularity of the pulse in mitral disease is indicated. All the points he raises receive ample illustration in the very carefully recorded cases with which the text abounds. The lecture headed "Curable Mitral Regurgitation" refers to the conditions present in cases of chlorosis, chorea, and fevers—conditions mostly referable to ventricular weakness. Dr. Balfour's views on the chlorotic murmur are well known, and his arguments in favour of its production in the auricular appendix rather than in the pulmonary artery, although much criticised, certainly afford a sufficient explanation of a difficult subject. There are lectures also upon murmurs in the pulmonary areas, and on variation and vanishing of cardiac murmurs, full of instructive and important matter. As to nervous affections, we note that he refers "cramp" to a fatal inhibition of the heart; and that he prefers in anginal diseases the inhalation of nitrite of amyl to the exhibition of nitro-glycerine. A lecture is also devoted to the action of digitalis and the therapeutics of cardiac disease. The author is strongly of opinion that digitalis is to be regarded as a cardiac stimulant, and he does not think that fatty degeneration contra-indicates its employment. Amongst tonics he speaks of strychnia, arsenic, and iron as the most useful, and he wisely insists on the importance of rest. The present volume contains additional matter in the lectures dealing with aneurism, and a reiterated statement of his belief in the value of treatment by iodide of potassium. On all these matters we must refer our readers to the work itself; it should not only be read but carefully studied, for we venture to think that all who do so will be amply repaid for their pains. They will not only gain a large amount of useful information, but will be led to think far more deeply of the changes, structural and functional, that the heart undergoes in adapting itself to the proper performance of its functions under the strained and altered conditions imposed by valvular disease. The result will be that, under the inspiration of the author, they will approach each case of cardiac disorder with a more profound interest, knowing what physiological problems underlie it.

*The Transactions of the Edinburgh Obstetrical Society.* Vol. VI.—The Edinburgh Society has this year for the first time published the work of one session in a separate volume. It is stated in the preface that this has been thought advisable by reason of the "greater bulk of its proceedings, during the past and present sessions, as compared with previous years." We heartily congratulate the Society on this step, for the volume represents an amount of work that would do credit to a much larger society than the Obstetrical Society of Edinburgh. The volume contains quarterly reports of the Royal Maternity and Simpson Memorial Hospital, but we will postpone our consideration of these to another occasion. Of the more interesting and valuable papers in the volume we would mention Dr. Hart's on the Shape of the Female Bladder; Dr. Macdonald's on Chronic Inversion of the Uterus; Dr. Napier's on Puerperal Temperatures; Dr. Halliday Croom's on a Complication of Occipito-posterior Position of the Vertex; and Dr. Turner's on Delivery by the Breech through a Flat Rachitic Pelvis. It is somewhat inconvenient to find a discussion in the present volume of a paper which we are told will appear in the next volume of Transactions; and we do not see the object of publishing in the Transactions of the Society a brief account of the diagnosis and treatment of ovarian tumours, a subject which is better and more fully treated in works on diseases of women, as well as in special treatises on ovarian diseases.

*Transactions of the American Gynecological Society.* Vol. VI.—The present volume of Transactions is perhaps

the best hitherto issued by the Society; it is, indeed, if we take it as a whole, a very valuable contribution to obstetric and gynaecological literature. The paper of Garrigues on Exploratory Puncture of the Abdomen is an excellent piece of work. It is based on a large number of observations made by himself, and the discussion of the material shows an extensive acquaintance with the literature of the subject. There is a long paper by Dr. Bozeman on the Treatment of Fistulæ of the Vagina, an interesting article by Goodell on Bursting Cysts of the Abdominal Cavity, one by Gaillard Thomas on Expansion of the Bladder over the Surface of Abdominal Tumours as a Complication of Laparotomy, and an interesting paper by Dr. Underhill on Jaundice in Pregnancy, with cases. The volume contains several papers a great part of which is historical. There is a tendency nowadays to commence papers by reviewing the past, and this in many cases is interesting and quite justifiable; at the same time, we think this is frequently overdone, and contributions would be far more valuable, far more interesting, and less wearying, were their authors to present their observations in as brief a form as possible, without the encumbrance of the usual historical introduction. There is a paper in the volume before us, of nearly fifty pages, on the Practice of Gynaecology in Ancient Times, which consists merely of extracts from ancient authors, showing their notions of the diseases of women and their modes of treatment. Interesting as the past must always be to men of culture, yet we fail to see that the Transactions of the Gynaecological Society is the place for such an abstract as the one before us, and we cannot see any reason for its publication in the volume.

*Skizzen aus der Chirurgischen Klinik des Herrn Professor Dr. Ritter von Nussbaum.* Von Dr. ISENSCHNEID. Erste Heft. Sommer, 1881. München: F. A. Finsterlin, 1882.—Dr. Isenschneid tells us in his preface that he has not made any attempt to give a detailed account of cases under Nussbaum's care, but has endeavoured to pick out those points of practice which had impressed him, and which would be likely to be of service to general surgeons. He accordingly gives brief, but careful, sketches of forty-eight cases which he saw treated in June and July of last year. The cases vary in severity from hypertrophy of the tonsils and retention of urine to excision of the jaw and laparotomy. They are recorded without elaborate detail, but by a competent observer who has grasped one or more points in them, and succeeds in presenting those points clearly. The sketches are very interesting, and full of practical instruction, and we are glad that Dr. Isenschneid promises a second instalment, double the size, in the course of the year. This second part will contain sketches of cases treated in the winter session 1881-82.

## New Inventions.

### A NEW OSTEOTOME, AND ELEVATORS.

THE Osteotome figured in the diagrams below is the invention of Mr. B. Campbell Gowan, a student at Guy's Hospital, who, it is almost needless to say, has devoted considerable time to the pursuit of practical mechanics before entering the medical profession. The instrument consists of two main parts. The first is a forceps (Fig. 1, c) with jaws working in a plane at right angles to the long powerful handle. With this the bone to be sawn is held. To render the hold on the bone secure, a thrust-rod (b) runs in the upper part of the handle, and its end presses upon and actuates the male or distal jaw of the forceps (f). On the upper edge of this rod is a thumb-piece, and on its lower edge it is toothed and is brought into gear with teeth on the pinion of a lever (d), which is fitted on below the handle. When the jaws of the forceps grasp the bone, the rod is thrust forwards with the thumb, and then by raising the lever (d) in the palm of the

hand, the thrust-rod is fixed and pressed still further home, and the jaws of the forceps thus made to grasp the bone immovably. The second part of the instrument consists of a long saw-blade and handle (a). The teeth are cut on the end of this blade, are double, and have a slightly forward direction. This is fixed on to the forceps by a pivot-slide (e), which has a pin on its back (not shown in the diagram),

FIG. 1.

which passes through a bush in the centre of the jaws, and keys the saw on to the forceps. On the front of the pivot-slide are lip-flanges, and the sides of the saw-blade fit accurately into them. With the forceps fixed on to the bone in the desired position and plane, the saw-blade is slipped down into this pivot-slide, and on until its teeth rest upon the bone. The saw is then at right angles to the handle of the forceps, and parallel with the blades, as shown in Fig. 2.

FIG. 2.

The surgeon grasps the forceps tightly in one hand, and works the handle of the saw to and fro in the only plane in which movement is free—viz., parallel to the sides of the jaws,—and the bone is rapidly and accurately sawn across. The instrument has been used at Guy's Hospital, and found to answer well. Its advantages are the firm hold on the bone, and the ease and rapidity with which a true section of a bone can be made without injury to the soft parts.

Mr. Gowan has also devised Elevators for operations upon bones. They are so shaped as to be easily passed beneath a bone, one on each side, and their curved ends fit into each other. When in this position, by depressing the handles, the bone lying on the other ends is at once pressed up into the wound.

The above instruments, which promise to be of considerable value, are made by Mr. Hawksley, of Oxford-street.

# THE LANCET.

LONDON: SATURDAY, NOVEMBER 11, 1882.

AN official communication has been received by our Solicitors from the Solicitors to the Corporation of Brighton. It runs as follows:—"We are instructed by our clients to request you to convey to Dr. WAKLEY their appreciation of the fair spirit which has prompted him to insert the whole of Dr. RICHARDSON's Report in your issue of the 4th inst., at what we know must have been a very considerable expense and occasioned him some inconvenience. We are instructed to take no further steps in the action."

The Mayor and Corporation of Brighton have, therefore, abandoned the proceedings which they impetuously commenced against THE LANCET for its critical remarks on the insanitary condition of the sewers and sewerage of that town. They have acted wisely. We printed Dr. RICHARDSON's "Report" simply because it seemed fair to the Corporation of Brighton to do so, and because the admissions and recommendations of Dr. RICHARDSON—as was the case with the admissions and recommendations made by Sir JOSEPH BAZALGETTE, the other authority consulted by the Corporation—supplied a full justification of our original and subsequent remarks and suggestions. Neither of these gentlemen has, in our judgment, hit on the right plan of amendment, but both acknowledge—Dr. RICHARDSON emphatically—that the ventilation of the sewers must be (to use his own adjective) "enormously" increased. In short, Dr. RICHARDSON and Sir JOSEPH BAZALGETTE agree in recognising that during a considerable portion of each twenty-four hours "the intercepting sewer" is tide-locked; and while the one would stud the town with air-shafts, "not less than four inches in diameter," the other would throw open the sewers "in at least twenty parts of the town," from man-hole to man-hole, covering the opening only with a grating; and both would rely on almost continuous pumping and flushing to get rid of the sewage. As we have said, neither of the recommendations made by the chosen advisers of the Corporation seems to us completely suitable or adequate; but it is not our function to solve the problem of local sanitation. We discharged our duty in pointing out the need that undoubtedly, and now admittedly, waits to be satisfied.

The Corporation having receded from a position which it ought never to have taken up, we can only wish the local authority well out of its difficulty. It was solely with a desire to help forward the reform which we knew, and what the people of Brighton now know, to be necessary that our criticisms were made. No consideration has ever yet deterred us from exposing what we believe to be remediable faults in the sanitation of any place of public resort, and nothing will induce us to abstain from an honest discharge of this function in the future. We were perfectly prepared to abide the issue of the proceedings which the Mayor and Corporation of Brighton unadvisedly instituted, because our

only desire has been to help in the remedy of an evil to which we trust the sanitary authority will now direct its undivided attention. That evil *must* be remedied. Delay is to be deprecated, and if the Corporation of Brighton is well advised it will, as soon as its differences with the authorities at Hove are settled, reconsider the whole question, *de novo*, with a calmer spirit and in a clearer light. The problem of reconstruction is confessedly one of exceeding perplexity, looking to the many and costly schemes which have been submitted. Our own idea, as expressed at the outset, is that the most complete sanitary reform, though it may seem to involve the largest outlay at once, will be cheapest in the end. Of this question of policy we are not, however, the arbitrators. All we have said, and now repeat, is that the sanitary condition of Brighton is faulty, and that it calls for a remedy which the Corporation should not, and we hope and believe will not, further hesitate to apply.

WE were not wrong in indulging a hope that the Government would be questioned on the subject of the Royal Commission on Medical Acts. In our Parliamentary report of last week our readers will see the answer of Mr. MUNDELLA to Sir TREVOR LAWRENCE, which on the whole is satisfactory. The Report of the Medical Commission is at present under consideration, but the Department had not arrived at such a stage in their deliberations as to enable Mr. MUNDELLA to state what course they proposed to pursue. We must remember that this answer was given on the 2nd of November, and that we are yet fully three months from the time at which any actual legislation can be proposed. No doubt the present suspense and tension of all the medical bodies and of the whole army of medical students are great, and ought to be relieved. Nevertheless, we must give the Government time to consider and deliberate.

There are a few facts on the very surface of this subject which cannot be too deeply considered. The first is, that there is an universal feeling that we have too many examining bodies, and that if legislation is to be efficient we must get rid of some of them. Sir JAMES PAGET—as readers of the evidence will see—puts this fact in the most kindly and euphemistic way. Plied by Mr. HUXLEY with the difficulty that a conjoint system would give a new Parliamentary title to certain bodies which "it may not be very desirable to perpetuate," Sir JAMES said: "I think with some of them it would be, on the whole, an advantage if they ceased. I have often wished that there was a timely mortality amongst institutions as amongst men."

But it is not only English medical reformers who think that the time has come for allowing some of the medical corporations to "fall on sleep." Here, at least, we have the concurrence of some, if not all, of our Scotch friends. Professor TURNER may be accepted as their mouthpiece, and he is decidedly in favour of disfranchisement, or, as Sir JAMES humanely puts it, "the timely death," of a few of the entirely superfluous corporations. In the special Memorandum by Professor TURNER appended to the Report of the Royal Commissioners (page 29) the following paragraph occurs: "As regards the two Societies of Apothecaries, I am of opinion that their existence as licensing bodies is an anachronism, and that they should in future cease

to take part in conducting examinations for a licence to practise."

The only difference between Scotch and other reformers in this matter is that the Scotch see their way clearly to drop an English and an Irish corporation, but cling to the hope of saving the superfluous one in Scotland from that timely death so feelingly desiderated by Sir JAMES for institutions that have obviously no further *raison d'être*, and can only be perpetuated by what is virtually a tax on the medical profession. It is surely an excess of patriotism to shield a superfluous corporation in a division of the kingdom with three corporations to four millions of people, while you are sacrificing one in another division where there are only three to twenty-five millions. Scotch liberalism will not make such a mistake in fairness and thoroughness.

The second fact is that there is an universal feeling in favour of a complete qualification diploma being given instead of the *half diplomas* which are now dispensed; that the diploma-granting bodies shall be reduced to three—one for each division of the kingdom; and that the curriculum, examinations, and fees of these Boards shall be as equal as in the nature of things it is possible for them to be. It is time that the mutual disparagement of licensing bodies should cease, and that men who hold their licence from a college in Edinburgh should not be taunted with holding an inferior document by those who hold their diploma from a college in London or Dublin. The legal privileges conferred by diplomas are the same in each division of the kingdom; so should be the knowledge guaranteed by their diplomas.

To this end the creation of a new Medical Council is indispensable—one in which Corporations shall cease to be individually represented. It would be monstrous that while being deprived of their individual licensing power, they should retain an individual representation on the Medical Council. The grouping of the undiafranchised corporations for examining purposes will necessarily carry their grouping for purposes of representation, as recommended by the Royal Commissioners. This will make room for another recommendation of the Commissioners, in regard to which the profession and the public seem unanimous, that the medical profession, apart from its cliques and corporations, should have a certain number of representatives. The public will not believe, with Mr. SIMON, that all these representatives will care about will be questions of pecuniary and professional advantage. Such a suggestion is little short of an insult to the profession, and comes with bad grace from Mr. SIMON. As experienced practitioners they will take their share in debating practical questions of medical education which have been very little advanced by the Medical Council.

UNDER the heading "Mansions of Death," a title somewhat vivid perhaps, but still not more so, we fear, than the circumstances fully justify, Mr. W. K. BURTON, a consulting engineer, addresses himself to the daily press, with a view of drawing public attention to the grave sanitary defects which characterise a large proportion of London houses. The story he tells as to the condition of houses in the neighbourhood of Mayfair, as regards their drainage, would hardly need to be altered if it were told of nine-tenths of the area of the metropolis, and it is probable that in one respect only do the modern houses materially differ from those which have

for several generations constituted the fashionable districts of London. This difference lies in the brick barrel drain, so often an elongated cesspool, which has within recent years been replaced by the use of ill-laid, ill-jointed, and hence leaky glazed pipes. Owing to the faulty manner in which London houses are grouped together, it is almost everywhere a matter of necessity that their drains should be carried beneath them in order to reach the sewer, and the various offices from which waste and other drain-pipes pass are often, sometimes through ignorance, but still more frequently from motives of architectural economy, so situated as to make it most easy to connect those pipes directly with the drain in the course of its passage beneath the dwelling. In every large and well-appointed house it thus comes to pass that several soil-pipes, a number of waste-pipes from housemaids' sinks, butlers' pantries, baths and lavatories, in addition to overflow pipes from some three or four cisterns, all connect the interior of the house with the interior of the drain; and the latter being rarely provided with a sufficient trap in its course to the public sewer, the house and the sewer itself come to be in direct communication with each other. The mansion, too, is far worse off than the cottage, for the larger the establishment the more numerous will be the pipes by which foul air is thus laid on from sewer to house. It is true that most of the drain connexions referred to are provided with some form of trap, but it is well known that even the most perfectly designed apparatus cannot be trusted to keep back noxious effluvia from the sewer, especially when there is a marked difference between the temperature on the house side and that on the sewer side of the trap. Hence we cannot too emphatically protest against the prevailing and misplaced faith in the power of traps to keep sewer-air out of houses. Between the interior of the house and the interior of the drain there should at every point be an absolute air-break; and traps, though serving useful purposes in connexion with waste and other pipes, should never be relied on to prevent the passage of drain-air, except at such drain inlets as are out of doors. The house-drain itself should be bedded in concrete, and otherwise rendered impervious to the passage of either foul air or sewage into the surrounding soil; it should be fitted with a syphon trap before its junction with the sewer, and it should be provided with two ventilating openings at different levels, so as to secure throughout its course a never-ceasing current of fresh air. The neglect of these precautions, so simple in themselves, and yet of such vital importance, is but too often a cause of unnecessary death, and still more frequently of conditions of ill-health, the removal of which is beyond the range of therapeutics. Families who take highly-rented mansions and houses for a London season soon find themselves suffering from malaise, headache, physical prostration, sore-throat, and other obscure symptoms, which are rarely attributed to their proper cause, but are almost invariably set down as the natural incidents of a life of exceptional gaiety, to late hours, and to a change of air; and it is only when some serious and often fatal attack of diphtheria or enteric fever results from the inhalation of the poisoned air, that the real cause of the evil is suspected. Too often it is even then most difficult to prove the relation between cause and effect. Houses, the air of which is hardly ever free from contamination, may yet never have

been the seat of really offensive effluvia, and it cannot be too widely known that offensiveness is by no means a necessary characteristic of those specially dangerous emanations which carry with them the poisons of the specific fevers. The more offensive gases are readily absorbed by the water-trapping, whereas particles of infection may pass into the air of the dwelling from the evaporating surface of the trap.

Nothing short of such structural arrangements as will with certainty ensure the exclusion of all sewer and drain air from dwellings can be regarded as sufficing for the protection of the public against the needless risk which they now run in houses, whether old or modern. In London the risk is perhaps at its greatest, and this because modern regulations as to building operations are much more readily adopted in country towns and boroughs, where the sanitary jurisdiction is in the hands of a single authority, than in the metropolis, with its divided rule and divided responsibility. But still London does not stand alone in this matter; the evil is widely spread. Indeed, it is at this season of the year especially that we learn most of disease and death brought about by similar faults in the sanitary arrangements of places which, by the very fact that they offer themselves as health-resorts, should be the first to eliminate from their midst conditions of house-construction so fraught with danger to life and health.

THE letter on the Report of the Royal Commission on Infectious Hospitals which has been addressed to us by Mr. PEARSON HILL, and which we publish elsewhere, raises a question of considerable importance in connexion with the future isolation arrangements for the metropolis. The Commissioners propose to set a limit to the number of small-pox patients to be aggregated on any one site; but, except in so far as a similar end may be arrived at by the division of London into hospital districts, each district to isolate its own cases of infectious disease, no such limitation is proposed as regards scarlet fever and the continued fevers. The ground for dealing differently with the two groups of diseases is, that in the one case—namely, small-pox—the aggregation of patients is known to have been followed by the spread of infection to the surrounding community; and in the other—namely, the remainder of the specific fevers—no such result has been recorded, and this in spite of the fact that thirty-two medical men having special acquaintance with the subject under consideration gave evidence before the Commission. Some positive evidence to the contrary was indeed adduced; especially that relating to the influence of the London Fever and the Warrington Borough Hospitals on the neighbourhoods in which they are situated. But this evidence, which is detailed in the recent official Report on the Use and Influence of Hospitals for Infectious Diseases, cannot, in some important respects, be regarded as sufficient to determine finally the question as affecting the hospitals belonging to the Metropolitan Asylums Board. Thus, taking the question of the isolation of scarlet fever, we find that in neither instance did the number of patients under isolation at any one time reach that which the Asylums Board hospitals are intended to receive; the highest numbers attained being at the London Fever Hospital, where a total of 103 scarlet fever patients were simultaneously under treatment in 1875, and a total of 108 in 1879. The matter

is somewhat different with regard to typhus and relapsing fever. Thus, in 1864 there were 168, and in 1865 there were 162 cases of typhus, and in 1869 there were 250 cases of relapsing fever, at one and the same time in the hospital; and notwithstanding the fact that the buildings are somewhat closely surrounded by dwellings, no case of the spread of either disease could be learned as the result of two inquiries. Taking scarlet fever, relapsing fever, and the several continued fevers together, the numbers simultaneously under treatment in the London Fever Hospital have been much larger. Thus, according to a table prepared by Mr. SHIRLEY MURPHY, it appears that on the last day of thirty-six months during the nine years 1862-70 the total number of such patients then in hospital varied from 200 to nearly 400, the highest totals reached being 369 on one occasion and 391 on another. But the fact that the patients in question, though in the aggregate numerous, suffered from different diseases, and were in consequence centres not of one but of several different specific infections, prevents any comparison being drawn between the results of their simultaneous treatment in one institution and the possible practice of large fever hospitals in the future. The fact remains that we have no sufficient evidence to show whether the aggregation of cases of scarlet fever and the other fevers beyond a certain point can be attended by results similar to those which followed on the simultaneous treatment of a considerable number of acute cases of small-pox at Fulham, and it is obvious that nothing short of an inquiry as minute and as painstaking as that which was made by Mr. W. H. POWER in the Fulham case will suffice to clear up the point.

We are hardly able to agree with Mr. PEARSON HILL in his contention that fever patients can be removed to distant hospitals with the same absence of risk as is the case with small-pox patients. Dr. MURCHISON's statement to the effect that the mortality amongst patients brought to the London Fever Hospital from a distance was no greater than that amongst those conveyed shorter distances, applied, we believe, solely to cases of typhus. As regards enteric fever, and indeed scarlet fever also, the matter is different. Thus the diagnosis of enteric fever is often not sufficiently certain to warrant isolation in hospital until a stage has been reached when a long journey would be fraught with much risk, and bearing in mind that removal to isolation hospitals is usually effected in the interests of the public, all unnecessary risk to the patient should be avoided. Dr. MURCHISON's writings go strongly to urge the avoidance of all unnecessary movement in the case of this fever; and the statement of the Commissioners, to the effect that long removals must not be risked even in cases that are not very severe, is, we think, fully borne out by experience. This, however, points, not to aggregation at large centres, but to the provision of small hospitals at reasonably available points.

WE observe with much satisfaction that Sir GARNET WOLSELEY in his despatch to the Secretary of State for War, forwarding for his information the names of those who, in his opinion, should be specially brought to favourable notice for the good work they did during the campaign, has not forgotten the medical officers. He says, "The Medical Department, under Surgeon-General HANBURY, C.B., has

done everything that could possibly be done for the care and comfort of the sick and wounded. The manner in which the wounded were removed from the fighting-line by the bearer-company was most satisfactory. The following officers are brought specially to my notice:—Deputy Surgeon-General J. EKIN; Deputy Surgeon-General W. G. N. MANLEY, V.C.; Deputy Surgeon-General J. A. MARSTON; Brigade-Surgeon O. BARNETT, C.I.E.; Surgeon-Major G. S. DAVIS; Surgeon-Major T. F. DWYER." We trust that in the distribution of honours these officers will not be overlooked. In addition to them, however, Sir GARNET WOLSELEY, in reporting upon his personal staff, brings to notice the medical officer who was specially attached to him, Brigade-Surgeon R. W. JACKSON, C.B., of whom he says, "Brigade-Surgeon JACKSON, C.B., who has seen service in all parts of the world, has, through the many wars he has taken part in, distinguished himself throughout by his coolness under fire, and by his zeal as a medical officer. I would venture to recommend him for special promotion." Mr. JACKSON served in the Crimea, the Indian Mutiny, and the Ashanti war, and has always been a zealous and efficient officer. But there is a serious difficulty in the way of his receiving the promotion for which he is thus recommended. Mr. JACKSON was placed upon the retired list in August last, in accordance with the provisions of the Royal Warrant of Nov. 27th, 1879, having attained the age of fifty-five. To replace him on the active list and promote him would be in direct contravention of the Warrant, would be an act of injustice to the officers—in number about thirty—over whose heads he would be promoted, would undoubtedly revive in the Department the feeling which existed before the late reorganisation that Royal Warrants were no guarantee that the rights of medical officers would be respected, and would establish a dangerous precedent, which hereafter might be considered applicable to the Army generally. It would also reflect most injuriously upon Sir GARNET WOLSELEY if one of his early acts as Adjutant-General were the direct violation of one of those Warrants which it is his official duty to administer, in order that he might reward an officer who had served on his personal staff. We feel strongly that Mr. JACKSON is entitled to his well-earned reward, but it ought not to be one which will inflict an injustice upon his brother officers, destroy their confidence in Royal Warrants, and bring discredit upon the highest military authorities. We trust that Mr. CHILDERS may be able to find some means of adequately recognising Mr. JACKSON's services without incurring so grave a responsibility.

ON Wednesday, at a meeting of the Wednesbury Sanitary Authorities, it was stated that, owing to the alarming outbreak of small-pox which has recently occurred in that district, upwards of £2000 had been expended in providing hospital tents and the maintenance of patients. The disease is being gradually stamped out of the district, and there are now only forty-two patients in the hospital.

At a meeting of the Election Committee of the Middlesex Hospital, held on Monday last, Mr. A. Pearce Gould was appointed Assistant-Surgeon, in the room of the late Mr. Lyell. By this appointment Mr. Gould is transferred from the Westminster Hospital, where he has been for the past five years Assistant-Surgeon and Lecturer on Anatomy.

## Annotations.

"Ne quid nimis."

### ROYAL COLLEGE OF PHYSICIANS.

AT the last meeting of the Royal College of Physicians the following resolutions, moved by Dr. Acland, were referred to a Committee to report upon. It will be seen that they contemplate a very important step in the system of licensing examinations, which, if carried into effect, may eventually solve the vexed question of a complete licensing board so far as England is concerned. It is premature, however, to discuss the subject until it has taken more definite shape. Meanwhile the profession and the Government also will await the result of the proposal with interest. The resolutions ran as follows:—

"1. That whereas the Royal Commission on granting medical degrees has now affirmed the principle of diminishing the number of examining boards for medical licences, the Royal College of Physicians takes the opportunity of reaffirming that principle, already adopted and acted on by it."

"That the President be requested to name a Committee to consider and report to the College at its next meeting, what combination the College can best enter into for examination purposes, so as to secure for England, without further delay, one complete Pass Examination Board, which shall be satisfactory to the profession, the Medical Council, and the Government."

"3. That the President be also requested to take such steps as he may see fit, in order to obtain for the Committee the fullest information on the matter referred to it, before the next meeting of the College."

THIS is not the first time that the College has moved in this direction, but now being no longer bound by the Conjoint Scheme (the five years' grace having expired), it is free to invite the co-operation of another licensing body in the furtherance of the desired object.

### THE REGISTRAR-GENERAL'S QUARTERLY RETURN.

THE public health, judged by the Registrar-General's mortality statistics, continues satisfactory, and shows a marked improvement upon that which prevailed a few years ago. With the single exception of the three months ending September, 1880, the national death-rate reported by the Registrar-General has been considerably below the average for the corresponding period in each quarter since the beginning of 1880. Indeed the English death-rate has been almost continuously below the average since the end of 1875, an improvement which it appears only reasonable to attribute in great measure to the stimulating effect of the Public Health Acts of 1872 and 1875, upon sanitary organisation, and sanitation in general. The English annual death-rate during the past summer, the Registrar-General reports in his Quarterly Return, just issued, did not exceed 17.7 per 1000 of the estimated population, which was 1.5 below the average rate in the ten preceding corresponding quarters, although it showed an excess upon the exceptionally low rate in the summer quarters of 1879 and 1881. In other words, the mortality last quarter was nearly 8 per cent. below the average, signifying that more than 10,000 persons survived the three months in England and Wales, who would have died had the average death-rate been maintained. The low death-rate during last summer was undoubtedly due in great measure to the unseasonably low temperature, which induced an unusually low rate of mortality from diarrhoea. The saving of life during the quarter from the low diarrhoea rate was, however, less than half the saving from all causes. The decrease of mortality was equal to 9 per cent. among

infants under one year of age, to 6 per cent. among children and adults aged between one and sixty years, and to 2.0 per cent. among persons aged upwards of sixty years. The death-rates from scarlet fever, "fever," and small-pox were also below the average, whereas those from measles, whooping-cough, and diphtheria showed a slight excess. The mortality statistics of the past quarter—the crude death-rate, the zymotic death-rate, and the rate of infant mortality—point conclusively to a continuance during the last quarter of the recent well-marked improvement in the national health.

### THE "SOCIAL EVIL" AND THE CONTAGIOUS DISEASES ACTS.

A GREAT deal of righteous indignation has recently been expended on the state of our streets, and particularly the Strand, in regard to morality and the obtrusive parade of the social evil. There was much need for an expression of public opinion on this subject. We doubt whether there is in any other city in the world so shameless a flaunting of vice as not only may, but must, be witnessed by any foot passenger from Charing-cross to Waterloo-bridge at almost any hour between noon and midnight. It is a disgrace to the nation that throughout this country, with the exception of a few garrison towns, nearly every "populous place" is an open hotbed of pestilent moral corruption; while for special blazonry of the social evil some districts of the metropolis could scarcely be surpassed. We are not exaggerating the extent of the nuisance, nor is the view we take of the subject dictated by a narrow-minded conventionalism. Matters have come to such a pass that the police are powerless to do anything in the matter; and the shameless proceedings of the women who infest our streets are more demonstrative at this present time than at any other within memory. The harm done to the interests of social morality by the tolerance of this evil cannot be readily estimated. The pharisaical and fatuous policy of the Middlesex board of magistrates has been, and still is, to close the special places of resort which the common women of London of all grades once frequented; and where, at least, they were out of sight and could be avoided. The effect has not been to sweep back the ocean, but to flood the land. By blocking the old channels they have simply inundated the surrounding districts. It is now impossible for any man who would not be molested to walk up the east side of Waterloo-place, on his way from east to west, after the business or pleasure of the evening. The crowd is as dense as would be found in any ordinary business thoroughfare at a particularly busy hour; and not only a majority of the persons composing the crowd, but, with scarcely an exception, all, are actively and noisily bent on vice. Nevertheless, the shrieking sisterhood, and the study philosophers and book-room philanthropists, who either themselves conduct, or meddle and muddle in, our domestic political affairs, are doing their utmost to prevent recourse to the only measure which would be of the slightest avail in staying the plague. Nothing short of the universal adoption of the Contagious Diseases Acts, placing this most contagious moral malady under the direct control of the police, can rid us of an evil which is destroying the young of both sexes. If the Acts to which we refer were in operation in the metropolis three-fourths of the young females who now loiter in the streets, dallying with vice, would be deterred from doing so by the fact that the practice they at present pursue with perfect immunity from risk or punishment, would then certainly bring them within the grip of the agents of the law. It cannot be doubted that the tolerance of habitual street-walkers induces young women who have not yet actually entered that class to mingle with them, and imitate their proceedings. Again, the worst members of the class itself would be compelled

either to abandon their present line of life, or at least to pursue it under conditions which would not augment the demand by increasing the supply. The time has come when—leaving the man's view of the question wholly out of account, as the agitators against these Acts are wont to leave it—the woman's aspect of the problem, and her interests, require the only practicable and effective solution; namely, extension of the Acts, and the placing of the public morals of the country under, we will not say magisterial, but police, control. For a prompt and unhesitating application of this remedy for the existing perilous and pitiful state of matters, it is now the duty of every order-loving citizen to appeal.

### THE ELECTRIC LIGHT.

BEFORE the electric light becomes, as it must soon become, the common illuminating agent of the period, a determined effort should be made to devise some mode of mitigating its peculiarly unpleasant intensity. The vibratile impulse of the electric force is obviously stronger than the delicate terminal elements of the optic nerve in the retina can bear without injury. We are wont to apply the adjectives "hard" and "soft" to light, and their significance makes them peculiarly appropriate. The electric light is too hard; it needs to be softened. The waves of motion are too short, and the out-stroke—so to say—joins the in-stroke at too acute an angle. This might doubtless be obviated by employing suitable material for globes and shades, but perhaps the best plan would be to break up and scatter the rays of light by reflection. If a small convex reflector were placed immediately below the light in the protecting globe, and one of larger dimensions above it, so as to secure a double reflection with ultimate divergence downwards and outwards, the effect would be to cause the "rays" of light to fall obliquely on all objects within the immediate area of illumination. This would perhaps obviate the need of coloured glasses, which the promoters of the electric light seem to dislike. Certainly there is a considerable sacrifice of power in the use of the opaline globe—so much, indeed, that some of the districts lighted by electricity displayed through this medium do not present any very obvious superiority over gas. We throw out the suggestion for what it is worth. Something must be done, for, as it is, the electric light is "trying to the eyes," which means that it is in danger of injuring them, and already there is reason to believe mischief has been wrought by its use. For true comfort there is nothing like the light given by the old-fashioned pure wax candle.

### THE TRAUMATIC ORIGIN OF LOOSE BODIES IN JOINTS.

IN France, and Germany especially, the statement that in falls and blows upon the knee or other joint a portion of the normal articular cartilage and bone can be broken off and remain in the joint as a "loose body," has met with much opposition. In England this view has met with more general acceptance, and in modern special treatises and text-books no doubt is thrown upon it. On the one hand, cases are cited where persons with apparently perfectly healthy joints have after a fall or other severe local injury shown all the symptoms of "loose body;" and it has been found in some cases that corresponding more or less exactly with the outline of the loose body is a gap in the joint surface of the femur and tibia. On the other hand it is alleged that in these cases, although there may have been no previous signs of joint disease, there were really outgrowths from the articular cartilage that were broken off by the injury. In the gradual enlargement of these supposed outgrowths, the pressure upon the opposed joint surface has caused its absorption to an extent corresponding to the size of the outgrowths. This view will be held by most surgeons to

be fanciful, and not to accord with the most simple and straightforward interpretation of the facts, and it has been rejected in this country. M. E. Poncet of Cluny has approached this question from the histological point of view in a paper in the last number of the *Revue de Chirurgie*. Here he states that in capsular "arthrophytes" a gradual transition from cartilage through fibro-cartilage to true bone is not unfrequently met with, that there is sometimes calcification of the fibro-cartilage quite distinct from true bone, that in all specimens a hilus or remains of a pedicle are to be seen, while in none is there any capsule of newly formed fibrous tissue surrounding the loose body. In true traumatic "arthrophytes" he found, on the contrary, no hilus or sign of any pedicle, but the body was surrounded by a thin cortex of newly formed fibrous tissue, while a section showed that the line of separation of the bone and cartilage was sharp and abrupt, and without any intermediate zone of fibro-cartilage. The bony matter, too, was always placed to one side of the body, and was never completely surrounded by cartilage, but partially in immediate contact with the cortex of fibrous tissue which was found to be histologically continuous with the cell tissue in the cancelli. These observations certainly afford a further proof that "arthrophytes" may be produced by injury to previously perfectly healthy joints. M. Poncet advocates the removal of "loose bodies" through a sufficiently free incision, but he disapproves of the subsequent use of a drainage-tube. Regarding the drainage-tube as solely intended to prevent the exudation from the wound passing into the joint, he endeavours to secure this object by suturing the synovial membrane with fine catgut, and closing the external wound in a similar manner. As M. Poncet mistakes the object for which the drainage-tube is used in such cases, his argument upon it is misleading. The tube is used to run off any excessive secretion from the synovial membrane that may be caused by the interference of the operation. M. Poncet's successful case only shows that in it this secretion of synovial fluid did not occur, and it would be rash in the extreme to argue from it to all cases of a like nature.

#### ABERDEEN UNIVERSITY.

THE opening of the winter session at Aberdeen University has this year been peculiarly interesting from the fact that no fewer than four professors were called upon for the first time to conduct classes within its walls. Three of these belonged to the Medical Faculty, and by a singularly happy coincidence, though the positions were vacant for various reasons, none of the gentlemen had to fill a blank caused by the hand of death. Through the retirement of the venerable Professor Pirrie, whose high services, enthusiastic character, and distinguished position were appropriately referred to by every speaker in his turn, the chair of Surgery has been left to Dr. Alex. Ogston, who commences his professional life amid high hope and after able work in the science and practice of his subject. Dr. Alleyne Nicholson succeeds Dr. Cossar Ewart, now of Edinburgh; and Dr. Hamilton has the honour not only of initiating the work in the chair of Pathology, founded through the munificence of Sir Erasmus Wilson, but of occupying a position unfortunately unique in the profession. The duties of the Pathology chair are quite as arduous as are those of the professor of the sister subject, Physiology, and, though the teacher of the latter science is not in all cases a pure physiologist, it is usually recognised as an advantage to his students and to science generally if he is not distracted by the cares of private practice. Sir Erasmus Wilson took a similar view with regard to the teaching of pathology, and has so handsomely endowed this chair at Aberdeen that the services of such a well-known pathologist as Dr. Hamilton could be obtained, and that gentleman is now the only teacher of pathology in

Britain who, by the rules under which he holds office, confines himself entirely to the elucidation of that subject. We have frequently drawn attention to the undoubted deficiency in most of our English schools arising from the subsidiary part which teaching takes in the lives of many of our best men; and if the generosity of Sir E. Wilson could be imitated and the financial difficulty overcome in these cases, it would be of vast benefit to scientific medicine. In any case, the teaching power has been greatly strengthened at Aberdeen by the institution of a chair of pathology—a subject which, both from its own importance, its rapid growth, and the lessening time left to its incidental treatment in other classes, demands separate consideration in any well-arranged curriculum. During the past few years the Aberdeen School has been subject to many losses, and graduates of a few years' standing would now find but few of the old teachers doing duty. There are but three chairs in the Medical Faculty occupied as they were in 1875, and two at least of these are filled by men of great vigour. A staff composed of men comparatively youthful, and thoroughly well chosen, should be equal to excellent work, and the new professors will have the best wishes of all interested in this northern school.

#### DRAINAGE AND TYPHOID IN PARIS.

AGAIN the grave increase of typhoid fever in Paris must call public attention to the extraordinary imperfections of the drainage of this "centre of civilisation." Most of the houses communicate direct at once with a cesspool and with the public sewers. That the water in these sewers is highly contaminated has been demonstrated over and over again by the death of all the fish in the Seine near the sewer outfall and by numerous analyses. No sink pipe is trapped in Paris, though it is sometimes conducted through the wall; where, as it measures only about two inches in diameter and joins the water-spout junction, which is some four inches in diameter, the connexion might be broken off and a sort of ventilation established. This, however, is carefully prevented by the use of a quantity of cement, so that the gases rising up the water-spout are conducted straight into the house, attracted by the higher temperature of the interior. Of late some of the iron pipes coming from the houses into the sewer have been bent upwards at their extremity, and form a sort of spoon which retains a little water and is supposed to act as a syphon. But this is a mere illusion, as there is no "dip" whatsoever to the syphon, and the slightest pressure or the smallest ripple over the surface of the water, caused by wind or the falling of a heavy substance, would suffice to break the seal. We may therefore safely assert that an enormous majority of the Paris houses are utterly unprotected against the injurious emanations from cesspool and sewer. Further, many closets are utterly devoid of water-supply, while in all instances the house drain-pipes are much too large, and therefore cannot be kept clean, particularly when the fear of overflowing the cesspool necessitates a stint of water. Over and above these considerations, the sewers themselves are so unsuitably constructed that they do not act, and it is consequently necessary to maintain, at great cost, an army of 800 men to literally push the heavy deposits along to the sewer outfall. Many of the small branch sewers also are so dangerous and foul that the men refuse to enter them, and these have to be left to engender disease, without even an effort to cleanse them. Finally, there is no organised method of ventilating the sewers. The necessity of sewer-ventilation has not yet been recognised, and what ventilation there may be is of a purely accidental description. In fact, the houses, by reason of their superior elevation and temperature, are the most active sewer ventilators that exist, and it is not till after the sewer-gas had been breathed by the inhabitants of the

apartments that it reaches the streets or open air. Of course, the more elevated quarters of Paris are subjected to a stronger pressure of sewer-gas, which in unventilated sewers generally tends to ascend to the highest points. Hence, typhoid fever is usually more prevalent at Montmartre, Batignolles, and along the course of the "collecteur du Nord." It will take many years and a large expenditure of money to remedy all these defects; still the evils might be modified to some extent by the immediate introduction of good syphons at the junction of the house-drains with the public sewers. Pending their reconstruction, the sewers might with comparative facility be ventilated, and police supervision could ensure greater cleanliness within the houses. All this could be done pending the adoption of some comprehensive and general scheme of drainage; and, though such measures would not suffice to place Paris on a par with modern principles of hygiene, still they would save many valuable lives. Considering the large number of Englishmen who frequent the French capital and, by their lavish expenditure, enrich the hotel- and shop-keepers of that attractive city, we have a right to complain of the risks our compatriots are compelled to incur when they visit Paris.

### THE PROPOSED CONVALESCENT HOME AT HASTINGS.

THE generous offer, by the Misses Briscoe, of the large mansion in White Rock Gardens, Hastings, to be used as a Convalescent Home for the patients of the infirmary and others, appears to be regarded with very mixed feelings by the parties concerned in the matter. By some it is looked on as a veritable white elephant. Owners of property in the neighbourhood of the mansion have issued a protest, threatening legal proceedings in the event of the premises being employed in the way suggested; whilst many friends of the infirmary seem to fear that the raising of the money necessary to maintain the Home will be effected with detriment to the financial interests of the former institution. The question of acceptance of the offer has been adjourned for six weeks, at the end of which time a committee of the infirmary is to be prepared with a report. Meantime it may be observed that trustees of charities are often placed in a difficult position by the offer of benefactions not exactly suitable to the object in view. Convalescent Homes are not well situated when in close contiguity with dwelling-houses. They should be placed in their own grounds, on an open breezy site, offering conditions most favourable to the restoration of the health of their inmates. If the mansion in White Rock Gardens could be disposed of for its full value and the money devoted to the erection of a building in a situation such as that described, the problem which the Hastings Infirmary Committee have to consider would, we think, receive a more satisfactory solution than any likely to be arrived at if the question is restricted within the limits which seem to be proposed.

### THE ACTION AGAINST DRs. CLUCKIE AND DOBIE, OF GREENOCK.

THIS action, in which £500 damages were claimed for the death of a child under chloroform, has ended, as might have been expected, in favour of the defenders. Proof was led before Sheriff Smith, and Drs. Macleod, Watson, and Dunlop, of Glasgow, and Drs. Wallace and Paton of Greenock, were examined at some length as witnesses for the defenders. At the conclusion of the proof, and after the agent for the pursuer had been heard, Sheriff Smith said that a grave attack had been made upon the professional skill, attention, and tenderness of two medical gentlemen, which was certain to subject them to considerable anxiety; and he considered it his duty, while

reserving his formal judgment until the extension of the shorthand-writer's notes, to take the earliest opportunity of relieving them of that anxiety, which he would do by pronouncing judgment at once. After stating that he had every sympathy with the bereaved parents, Sheriff Smith proceeded to say that he considered that it had been proved that the death of their girl had resulted from the visitation of Providence, and that no blame had been brought home to either doctor. In this case it was evident the chloroform had been administered with the utmost care and skill, and with every possible precaution, and that the parents were totally wrong in attaching any blame to Dr. Cluckie and Dr. Dobie. He had therefore no hesitation in pronouncing decree of absolvitor in favour of both defenders. Drs. Cluckie and Dobie will have the sympathy of the whole medical profession in the annoyance to which they have been subjected. The Glasgow Medico-Chirurgical Society have requested their Council to take such steps as they may deem necessary, either alone or in concert with the Council of the Faculty, to initiate a subscription for the purpose of assisting in defraying these gentlemen's expenses. It is to be hoped that the response to this appeal will be prompt and liberal.

### VICTORIA UNIVERSITY AND MEDICAL DEGREES.

ON the 1st instant the Manchester University conferred its degrees in arts and sciences on a numerous body of graduates for the first time since the date of its charter, in April, 1880, by which from a simple college it was converted into a university, for at present Owens College is practically the Victoria University. The graduates were all previously associates of Owens College, and have merely changed their academical title; and it is greatly to the credit of the College that so large a number of well-known literary and scientific students should have been ready for enrolment in the ranks of the new University. This proves most conclusively that no real hardship existed, for almost all these gentlemen already held degrees from other universities, and it shows that degrees by the best class of students are readily obtainable at the older universities and examining bodies. We are, however, more particularly concerned with the motion of Professor Roscoe, in accordance with which a petition to the Queen in Council was adopted, asking for the grant of a supplemental charter to enable the Victoria University to confer degrees and distinctions in medicine and surgery. The chief point in the petition is reserved for the last sentence; the preceding paragraph referring to the staff and the students can scarcely be seriously urged for when the teaching-staff is no larger, and the number of students no greater, than in some of our metropolitan schools who advance no such claims for giving medical degrees. This sentence runs thus:—"Your petitioners believe that it would not only complete the powers and increase the usefulness of the University which Her Majesty has been pleased to found, but also that it would have the effect of raising the standard of medical education, particularly in the North of England, and would promote the advancement of medical science if the power to confer degrees in medicine and surgery were granted to the Victoria University." The utility of the University will not be impaired if the degrees, which we merely look on as a bait for additional students or a desire "to brand one's own herrings," be refused, for we are quite sure, not only that there are degree-giving bodies enough already in Great Britain and Ireland, but that an additional one will only be made use of as a precedent for other ambitious medical schools and colleges to press forward their claims for the same privilege. If the Victoria University grants medical degrees, why should not Liverpool and Birmingham, and even Bristol in a few years, make similar demands? Why

should King's and University Colleges, St. Bartholomew's and Guy's Hospitals, not ask for similar rights now? At present, the medical education of the degree-desiring student in these schools does not differ in any essential feature from that at Owens College, and every argument used in favour of the latter is equally applicable to them. The American system of granting medical degrees is surely a sufficient warning against their needless multiplication in this country. We fail to see how, with the universities of Scotland in one direction and those already established in England in the other, medical education can be raised in the north of England by the mere granting of an M.D. or M.S. degree by the Victoria University. It will be raised by the superiority of the teaching, not by the adventitious influence of the distinction.

#### THE MILLER MEMORIAL HOSPITAL.

IN October, 1881, nearly sixty members of the medical profession, residing and practising in the district of the Royal Kent Dispensary, unanimously certified that it would be of the greatest possible benefit to the neighbourhood if hospital accommodation in connexion with that institution were provided, and expressed their pleasure at hearing that a project was on foot to build a hospital wing. On the receipt of this communication, a conference was arranged between the Executive Committee of the Royal Kent Dispensary and the Canon Miller Memorial Fund Committee, which resulted in an arrangement by which it was decided to combine the two movements on the understanding that one of the wards in the proposed hospital should be called the "Miller Memorial Ward," as a recognition of the valuable services rendered by the late Rev. Canon Miller, D.D., as the originator of "Hospital Sunday" at Birmingham, and as a mark of esteem and affection to his memory. Mr. Wm. Bristowe of Greenwich was appointed honorary secretary, and by his exertions between £2000 and £3000 has been promised or paid towards the £5000 which it is estimated will be required to defray the expense of erecting the proposed hospital. We wish this movement all success. Few people have done more for the hospitals than the late Canon Miller, and he was one of the first to actively support the proposal of THE LANCET to establish Hospital Sunday in London.

#### PROPHYLAXIS OF TYPHOID FEVER.

At the sitting of the Paris Academy of Medicine, on the 24th ult., a discussion arose upon the prophylaxis of typhoid fever, the prevalent epidemic, doubtless, evoking the question which was introduced by M. Marjolin. He referred to the unhealthy dwellings of the poor, which no one thinks of improving, and urged that the various Commissions d'Hygiène should be empowered by law to take prompt action in remedying these defects. He charged the Assistance Publique with having, in violation of sanitary principles, suffered the wards of hospitals to be overcrowded with cases; and he criticised the measures recommended by the Committee of Public Hygiene as being impracticable. Isolation, he said, was difficult, especially among the poor and large families, when to carry it out provision should be made for the case of the members of the family who escaped the disease during the isolation of those attacked by it. Measures should also be adopted for the distribution of disinfectants; and M. Marjolin considered that the medical profession should make its voice heard in insisting upon legislation to improve the present deplorable state of things. M. Larrey said that the members of the Council of Hygiene were fully aware of the distress in certain districts; and account should be taken of the difficulties surrounding the question. He had often insisted that the law dealing with unhealthy dwellings should be

put in force, but this had not been done, and now that an epidemic of typhoid fever was before them, something must be done. The regulations adopted by the Council of Hygiene in a certain measure answered to the present emergency. M. Bouley thought it the duty of the Municipal Council to remedy the deplorable condition of dwellings in the outskirts of the city, where the artisan population were crowded together. Even if necessary, let houses be constructed and well-ventilated pavilions erected on sanitary principles. M. Dujardin Beaumetz pointed out that medicine could not undertake the work of demolition of unhealthy tenements. He thought that, besides unhealthy dwellings, the numerous permanent earthworks in Paris were to blame in the propagation of the fever. M. de Perrin said that barracks had never been the focus of an epidemic of typhoid fever. M. Proust reproved M. Marjolin for his censure of the Council of Public Hygiene. The instructions issued by the Council were based on scientific principles. Before solving the question of the prophylaxis of typhoid fever, before commencing improvements in unhealthy dwellings, the service of public hygiene in France should be remodelled. M. Marjolin, in reply, said he was pleased to find that all agreed with him as to the urgent need for the strict enforcement of the law relating to sanitation.

#### PERILS OF RAILWAY TRAVELLING.

WE have long contended that a perfect and ready means of communication between the passengers and the guard or driver of a train is necessary to public safety. It must be obvious that such a provision is absolutely indispensable as the first condition of possible escape in case of peril; but what, we must now ask, is the use of a means of communication the most perfect, if when an alarm is given the guard or driver is to deliberate and determine whether he will or will not act upon it? The instruction to engine-drivers to hesitate and look back along the line before they bring the train to a standstill, is one that ought to be peremptorily interdicted. It was a most insulting offence against public opinion to issue such an order, and we are wholly at a loss to understand how any respectable Board of Directors could have been found to sanction so flagrant an imposition on the public—we can describe it by no other term—as the provision of a means of communication, such as it is, and a private instruction to engine-drivers to delay, and use their own judgment, in obeying it. Let the fine for stopping a train without sufficient reason be made as heavy as directors please, let it even be made a misdemeanour to do this; but the travelling public must at all costs and inconveniences, feel assured that they can instantly communicate with guard or driver in case of need, and that having received the order or heard the alarm, the summons to stop shall be immediately obeyed.

#### XANTHIC OXIDE URINARY CALCULUS.

DR. G. L. PORTER, of Bridgeport, U.S., has had under his care a young woman who had several attacks of renal colic; after one of these attacks she passed per urethram a calculus one inch long and half an inch in breadth. The stone was of a yellowish colour, and on analysis proved to be composed of xanthic oxide. It was shown at a late meeting of the New York Medical and Surgical Society by Dr. R. F. Weir. This is the rarest of all forms of urinary calculus, and this specimen is only the eighth that has been recorded. Dr. Marcet was the first who discovered this substance in a urinary calculus; Langier recorded a second specimen; Langenbeck removed the third, and the second largest yet noted; it weighed 338 grains, and was analysed by Liebig. The Museum of the College of Surgeons contains half a calculus that was presented to it by Mr.

Bransby Cooper, who obtained it from a surgeon who had removed it in India; its nature was discovered by Mr. Taylor. Mr. Fleming, of Dublin, and Dr. Dulk have also recorded specimens. Dr. Gaillard has removed a xanthic calculus weighing 350 grains, the largest on record. Xanthic oxide is closely allied in composition to uric acid, and its formation is believed to be due to imperfect oxidation of nitrogenous material.

#### POISONING FROM BRAWN.

DR. THURSFIELD, in a report addressed to the Whitchurch (Salop) Urban Sanitary Authority, draws attention to a serious group of symptoms from which seventeen persons suffered in September last as the result of eating some brawn. The persons affected had absolutely nothing in common except the consumption of this article of food, and the brawn when examined microscopically was found to contain, in addition to the ordinary bacteria of decomposition, other apparently distinct micro-organisms, which were capable of similarly affecting other pieces of meat to which they were applied. The organisms are described as of the most minute kind, and they were found in brawn which had been procured from two entirely different shops on the same day. That they were related to the symptoms as cause to effect does not, according to Dr. Thursfield, admit of doubt. But crucial evidence as to this would have been forthcoming had Dr. Thursfield been able to administer a small quantity of the affected article to one or two mice, a proceeding which is rendered impossible by the stringent terms of the Vivisection Act. All the persons affected exhibited a distinct period of incubation between the consumption of the brawn and the onset of their symptoms, and the worst attacks occurred in those who ate the brawn some days after it was made. Nothing could be learned to show that the animals from which the brawn was made were otherwise than healthy; all seems to point to some subsequent infection of the flesh. Two years ago six very similar cases occurred in Whitchurch, two of them proving fatal; and as it was then assumed that the symptoms were due to some form of poisonous matter capable of being detected by chemical analysis, the brawn was on this occasion submitted to the county analyst, with the result that it was found to be absolutely free from any mineral poison. Such instances as these, taken together with the series of similar occurrences at Welbeck and at Nottingham, point to a danger associated with the consumption of pork in its various forms, which does not appear to attach to the flesh of other animals, and also to the need for very careful inquiry into the whole subject.

#### DR. SOUTHON, CENTRAL AFRICA.

A GREAT loss has befallen the cause of medical missions, which is eminently the cause of civilisation, in Central Africa. We have seldom read a short piece of biography with greater interest than we felt in reading a brief account of the late Dr. E. J. Southon, medical missionary, Urambo, Central Africa, including, alas! the story of his death, after an accidental gunshot wound of the elbow, and amputation by Mr. Copplestone, of the Church Missionary Society at Uyui. In the absence of a full account of this remarkable man's life, we commend this paper to our readers. It is to be found in the current quarterly paper of the Edinburgh Medical Missionary Society. Dr. Southon had acquired a great influence over the King Mirambo, owing to his surgical services in the removal of some tumours from the King's arm. He was deeply engaged, too, in the study of the Kinyamwezi language, which, at the time of his death, he had so far reduced to writing as to be able to compile a small "reader" for his pupils, who included thirty sons of chiefs. His diary gives a remarkable idea of the multifarious work

in which he engaged—from preaching, or removing tumours from the King's arm to the making of a hut or the taking of meteorological observations. We can only express the hope that the notices of his life, which are to be found in the missionary journals, will be amplified into one fuller and complete, and that his work will be taken up by some worthy successor of a man whose life and death remind us more of Livingstone than anything which we have read since the death of that devoted man.

#### THE ROYAL SOCIETY.

THE following is the list of names nominated for the Council of the Royal Society to be balloted for on November 30th:—President, William Spottiswoode, D.C.L., LL.D.; Treasurer, John Evans, D.C.L., LL.D.; Secretaries, G. G. Stokes, D.C.L., LL.D., Professor Michael Foster; Foreign Secretary, Professor A. W. Williamson, LL.D. Other members of the Council:—Professor W. G. Adams, F.C.P.S., John Ball, F.R.A.S., T. Lauder Brunton, M.D., Professor Heinrich Debus, Ph.D., Francis Galton, F.G.S., Professor Olaus Henriki, Ph.D., Professor Huxley, LL.D., Professor E. Ray Lankester, Professor Lister, Professor Prestwich, F.G.S., Professor Osborne Reynolds, M.A., Professor Roscoe, The Marquis of Salisbury, Osbert Salvin, M.A., F.L.S., Warington W. Smyth, M.A., F.G.S., Edward James Stone, M.A., F.R.A.S.

A Royal Medal has, we learn, been awarded to Professor Flower, LL.D., F.R.S., by the Council of the Society in consideration of his numerous and valuable contributions to science.

#### LONDON IN NOVEMBER.

THE autumn session of Parliament will, among other beneficial results, probably help to reduce the erroneous impression which pervades many minds that London is intolerable as a place of residence in the later months of the year, particularly in November. Nothing can well be further from the truth than this wide-spread notion. As a matter of fact, the metropolitan district is at very nearly its best in October and November and a portion, at least, of the month of December. The worst month of the year—the typical modern year we mean—is, probably, that in which the Houses of Parliament are usually opened: February. March and April are scarcely less wretched. It is exceedingly unfortunate that the prejudice which undoubtedly exists cannot be removed. Trade suffers and society is disorganised quite needlessly in the two months before Christmas by the unanimity with which the Upper Ten avoid London at the very time when it is, on the whole, at its pleasantest. Those who are compelled to remain in town at this season are not sorry that the political exigencies of the year 1882 have obliged a considerable number of Members of Parliament to make the acquaintance of the capital at a time when they usually avoid it.

#### SOUTHEND-ON-SEA.

THE question of laying on the water of the Southend Waterworks Company to an outlying part of this health-resort, which is known as Prittlewell, is causing much discussion. In 1880 Prittlewell suffered from a considerable epidemic of enteric fever; the wells were found to be sunk in a porous soil, which had for generations received the soakage from pervious cesspits, and the use of water thus polluted was ascertained to have been the main cause of the epidemic. At that time the people were thankful to avail themselves of a supply sent daily from Southend in water-carts, and on more recent occasions when a scarcity of water has prevailed a similar method of supply has been resorted to. The Water Company, in consequence of the prospective

demands which will be made on their supply, have at great cost sunk a new deep well at Prittlewell, and their mains have been laid through the village. But when the question of making the house connexions arises, the inhabitants, forgetting the bitter experience they went through in 1880, declare that in their dangerously placed wells they have a supply of pure and wholesome water sufficient for all domestic and sanitary purposes, and they petition for a Government inquiry. One was held in 1880, and the wells were condemned; a second one would hardly convince the petitioners.

#### THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

At the meeting of the 14th inst. of the Society the paper of the evening on Endemic *Hæmatobia* will be illustrated with specimens of the *Bilharzia hæmatobia* in its several forms by Drs. Cobbold and Crocker. This opportunity will be taken to bring before the Fellows a numerous exhibition of animal parasites. Mr. A. P. Thomas of Oxford will describe his recent discovery, of the life history of the sheepfluke, exhibiting the small snail which is one host of the animal before it reaches the sheep. Drs. Cobbold, Bastian, Ray, Lankester, and Stephen Mackenzie, have also promised most interesting contributions to the exhibition of parasites.

#### SIR THOMAS WATSON, BART.

THERE has been a continuous loss of strength during the past week. On Tuesday Sir Thomas Watson complained of pain in the region of the bladder, with much irritation, the secretion being acid and depositing uric acid. The pain and irritation continuing through Tuesday night and Wednesday, he felt convinced that he had stone in the bladder, and requested Dr. Walters to telegraph for Mr. Lister, who promptly obeyed the summons, and relieved him by emptying his bladder with a catheter.

#### THE EDINBURGH GRADUATES' CLUB.

A FULL meeting of this pleasant club met at St. James's Restaurant on Wednesday evening. The dinner was good, and included an excellent specimen of that "great chieftain o' the puddin'-race," a haggis. The chair was occupied by Dr. Crawford, the Director-General of the Army Medical Department. The toasts were few and the speeches short, which added to the sociality of the evening. The toasts of the Army and Navy and the Health of the Director-General were received with great enthusiasm. The former was proposed by Dr. Crichton Browne, and the latter by Sir Joseph Fayrer.

#### MEDICAL HONOURS.

THE air is charged with rumours of coming honours to medical men, some long expected, and some that, if realised, will occasion criticism. We shall be disappointed if a Liberal Ministry in this matter does not devise liberal things, and advise a more deep and ample recognition of medical service and scientific merit than has yet been awarded to medical men in this realm. Ours is, probably, the country in which least honour is paid to that profession which saves life.

THE applications for space at the Berlin Hygienic Exhibition, which opens May 1st, 1883, have been so numerous that the promoters have had to contemplate an extension of the building ground by taking an adjoining site.

THE death is announced of Dr. Troschel, Professor of Zoology at Bonn.

THE names of Sir Peter Benson Maxwell, Knight, and Colonel Charles Brisbane Ewart, C.B., R.E., have been placed on the Royal Commission appointed to inquire into and report upon the system under which sewage is discharged into the Thames by the Metropolitan Board of Works.

WE regret to learn that during the gale which broke over Dorchester on Sunday last Mr. Good, whilst visiting his patients, was carried off his feet from the pavement into the roadway, and in falling suffered dislocation and fracture of an arm, besides other injuries.

THE Lord Chancellor has, on the recommendation of the Lord-Lieutenant, appointed Dr. Alfred Meadows, of Poyle Manor, Colnbrook, and George-street, Hanover-square, one of the magistrates for the county of Middlesex and the city and liberty of Westminster.

THERE appears to be no doubt that cholera has prevailed in an alarming manner at Mecca, and that it had extended to Jeddah, where many cases are reported to have occurred. Quarantine regulations are being enforced by the Egyptian Government.

THE whole of the scientific world will hear with regret of the illness of Professor Virchow. The latest report, however, is somewhat reassuring.

DR. BRAXTON HICKS has been elected Honorary Fellow of the Edinburgh Obstetrical Society.

## Public Health and Poor Law.

### LOCAL GOVERNMENT DEPARTMENT.

#### REPORTS OF MEDICAL OFFICERS OF HEALTH.

**Fulham.**—This district, which comprises the parish of Fulham and those of St. Peter's and St. Paul's, Hammersmith, had an estimated population of 116,000 in the middle of last year, and, excluding the deaths of non-parishioners which occurred in the Fulham small-pox hospital, the death-rate amounted to 19.3 per 1000 living. The deaths under one year of age were at the rate of 15.7 per cent. of the registered births, a rate which must be regarded as high, considering that the district is by no means one of the poorest or most densely populated of the metropolis. The history of the small-pox epidemic, both as affecting the isolation arrangements for the metropolis and as regards its incidence in the Fulham district, is told in considerable detail by Mr. Collier, who shows that the total mortality from this disease in his district was forty-four, and who alleges that whereas, when patients were removed to hospital directly it was known they were suffering from that disease, hardly a single case occurred in which there was any further spread of infection; yet, on the other hand, where cases were, either from accident or otherwise, not so removed, further attacks in the same house almost invariably resulted. Enteric fever was somewhat prevalent during the year, causing thirty-three deaths, as opposed to seven in 1880, and this not including some fatal attacks of so-called simple continued fever. As regards this disease, Mr. Collier points out how very undesirable it is, in the interests of the patients, to move the sick any considerable distance, and he considers that for this purpose every sanitary authority should have a hospital which is easy of access. Pig-keeping is still a source of great nuisance in the vicinity of Latymer-road, but owing to the great unwillingness of aggrieved persons to support the authority in dealing with this matter by tendering evidence before the magistrate, preventive measures are all but at a standstill.

**Hampstead.**—According to Dr. Edmund Gwynn's annual report for the parish of St. John, Hampstead, it appears that the last census return gave the population of the parish as 45,436, and at that estimate the death-rate for 1881 must be regarded as one of the smallest on record; for, including non-parishioners who died in the various local institutions, it was only 13·2 per 1000. It is true that, owing to the closing of the Hampstead Hospital, the number on which this rate is calculated did not include any fatal cases of infectious diseases removed from houses elsewhere than in the parish to any hospital belonging to the Asylums Board. But as regards small-pox, for which disease that hospital was originally used, it appears that, including all cases sent to the various small-pox hospitals, only six fatal attacks occurred amongst the population of Hampstead. And this leads Dr. Gwynn to show, in the form of a table, the small-pox death-rate in his district during the last two small-pox epidemics. In 1877-78, when the Hampstead Small-pox Hospital was open, the mortality from that disease was at the rate of 9·7 per 1000 of the population; whereas in 1880-81, during which period the hospital was closed, it was only 2·1 per 1000. The latter epidemic was, however, not as fatal as the former one as regards the metropolis as a whole, and therefore it could hardly be expected that, even had the local circumstances remained the same during the two periods, their mortality for the two periods in question would have been alike in Hampstead, and this especially in view of the large amount of protection afforded by increased vaccination during the period of the former period. Still, making every allowance for these and other possible sources of error, no question can remain but that the difference in the death-rate of the two periods must be regarded as to a great extent due to the different conditions, as regards the local aggregation of small-pox cases, which existed in the parish. And this view becomes even more convincing when it is remembered that crowded neighbourhoods such as Fleet-road, which suffered so much in the first epidemic, have, although now still more populous, all but entirely escaped during the recent outbreak; and that the streets and parts bordering on the grounds of the hospital did not in 1880-81 contribute a greater number of cases than the other parts of the parish, as was the case in 1877-78. As regards scarlet fever, Dr. Gwynn points to a circumstance which has been noted before, but concerning which no sufficiently definite information is as yet available; it is that the emanations from manure tend to the development of scarlet fever, and he points out how a number of the fatal attacks in Hampstead occurred in mews. The number of such attacks was, however, only nine out of a total of forty-seven in the parish as a whole; and it must be remembered that the facilities which children who play together in mews would have of contracting infection are very exceptional. In connexion with the prevention of the spread of infection, a Ransom's disinfecting stove has been provided; it has been in efficient working for some time, and is available for use by all in the parish. The charge, however, for such use is considerable, especially when it is remembered that the apparatus has been provided and is maintained at the public cost. Thus 15s. is the sum charged for the disinfection of bedding, &c.; and though the charge is to be remitted in the case of persons who are too poor to pay it, yet the uncertainty as to whether it will be claimed or not will probably to an important extent prevent the use of the stove, and so lead to what will now be an altogether unnecessary source of infection. Many parishes of London are still much in arrear of other sanitary districts, where in such matters the public, and not the unfortunate individuals who have already suffered, pay for the measures deemed necessary for preventing the spread of infection to the community at large.

**Huddersfield (Urban).**—Dr. Cameron's report upon the health of the borough of Huddersfield during the quarter ending September derives additional interest from the information it contains relative to the exceptionally fatal epidemic of measles from which that town has recently suffered. The annual death-rate during the quarter did not exceed 23·1 per 1000, but showed an increase of 6·6 upon the rate in the corresponding period of last year. A large portion of this excess was due to the measles epidemic, to which Dr. Cameron attributes 49 deaths, being four less than those reported by the Registrar-General during the thirteen weeks ending September 30th. The death-rate from measles in Huddersfield during last quarter was more than seven times as high as the mean rate in the twenty-eight large towns. The disease became epidemic during the latter part of June,

and the rate of fatality increased steadily until it reached its maximum in August. Of the 49 fatal cases, 39 were of children under two years of age, 8 of children aged between two and three years, and 2 of children aged three years. In most of the cases lung diseases were assigned as the secondary cause of death, and Dr. Cameron notes that, following the sharp outbreak of measles in the central registration district, the rate of mortality among young children from bronchitis, pneumonia, convulsions, and diarrhoea showed a marked excess; this is, with reasonable probability, attributed in great measure to the effects of the measles epidemic. It is most satisfactory to hear that the lesson of this epidemic, or rather of its unwonted mortality, has not been missed. The "circumstances pointed to, such a condition of unhealthiness in certain parts of the town," that the medical officer made a special report to his sanitary authority, and measures were at once adopted, which have resulted in a considerable improvement in its condition. Apart from the mortality from measles, the death-rate from other zymotic diseases was not excessive, and was considerably below the mean rate in the twenty-eight large towns. The rate of mortality from diarrhoea, although higher than that recorded in Halifax, was considerably below that prevailing in the other large Yorkshire towns. The Borough Hospital for Infectious Diseases contained 25 patients at the end of September, 36 having been admitted during the quarter. It appears that 52 cases of infectious disease were noted during the quarter under the 64th clause of the Huddersfield Improvement Act; this number is, however, considerably lower than the number of deaths from the principal zymotic diseases during the quarter. Dr. Cameron, in concluding his report, expresses his conviction that the Town Council will have no reason to grudge the increased expenditure which the special measures taken to improve the sanitary condition of the town have necessarily entailed.

**Leeds.**—Dr. Goldie's report for the third quarter of the present year refers to an undue prevalence of fever during that period, a result which, in his opinion, is owing to the absence of heavy rainfall, so much needed to secure powerful means for flushing the sewers. Dealing with an outbreak of small-pox, it is shown to have had an exceptional incidence upon shopkeepers, probably owing to the fact that infected persons were allowed to travel about the town. Up to the end of September last as many as 170 persons had been attacked, and the disease was still spreading. In the emergency the Leeds Borough Hospital has been opened for cases of small-pox, and as yet forty patients have been admitted.

**Paddington.**—The total population of Paddington in 1881 was 107,218, it having increased at the rate of 27·7 per cent. in the decennial period 1861-70, and at the rate of 10·7 per cent. in the last ten years. The birth-rate during last year amounted to 26·6 per 1000 living, and the deaths were at the rate of 15·7 per 1000, as opposed to 21·2 for London as a whole. One death from typhus was recorded in the year; and typhoid fever, which was specially fatal, caused twenty-one deaths. The cases of small-pox which occurred were, as far as possible, at once removed to one or other of the hospitals belonging to the Metropolitan Asylums Board, or to the Small-pox Hospital at Highgate; and in a similar way the London Fever Hospital was used for fever cases. In addition to numerous statistical tables which are appended to the report, Dr. Stevenson gives some useful information concerning the London water-supply.

**Cork.**—During the four weeks ending October 7th the total number of registered deaths amounted to 116 (including 25 in the workhouse, and therefore outside the borough); of these, 5 were due to infectious diseases. The births during the same period numbered 152. The mortality was equal to 19·02, but omitting the workhouse deaths it was 15·0. The returns compare favourably with those for the corresponding period of last year, both as regards the general mortality and the prevalence of fever in the city, the total and the urban death-rate being then 22·06 and 18·24 respectively, as against 19·02 and 15·0 now recorded.

#### BANGOR LOCAL BOARD.

The Board has decided that, in view of an outbreak of scarlet fever, the hospital tents erected for purposes of isolation of typhoid patients should remain standing. It was also proposed and agreed to that a plan and estimate should be prepared for the extension of the sewer outfall to the river Cegin.

The Woodford Local Board has agreed to adopt the sewerage scheme proposed by Mr. Angell, C.E., the cost of which, without purchase of site, is estimated at £15,000. The outfall will be situated on the eastern side of the river Roding. A committee has been appointed to report to the Board their opinion as to the best system for the treatment of the sewage.

### VITAL STATISTICS.

#### HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns, 6148 births and 3451 deaths were registered during the week ending the 4th inst. The annual death-rate in these towns, which had been equal to 20.5 and 21.4 per 1000 in the two preceding weeks, was 21.3 last week. The lowest death-rates in these towns last week were 15.2 in Brighton, 16.9 in Huddersfield, 17.3 in Newcastle-upon-Tyne, and 17.4 in Cardiff. The rates in the other towns ranged upwards to 26.2 in Oldham and Derby, 28.5 in Sunderland, 29.5 in Liverpool, and 33.1 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns were 483, showing a further slight decline from the numbers in recent weeks; 116 resulted from scarlet fever, 97 from measles, 93 from diarrhoea, 84 from "fever," 70 from whooping-cough, 21 from diphtheria, and only 2 from small-pox. No death from any of these zymotic diseases was recorded in Huddersfield, whereas they again caused the highest death-rates in Preston and Sunderland. Scarlet fever showed the largest proportional fatality in Sheffield and Sunderland; measles in Norwich and Sunderland; whooping-cough in Bradford and Preston; and "fever" in Portsmouth, Derby, and Sunderland. No fewer than 13 of the 28 deaths from diphtheria in the twenty-eight towns were recorded in London. Small-pox caused 1 death in West Ham (situated in the outer ring of suburban districts) and 1 both in Manchester and in Newcastle-upon-Tyne. The number of small-pox patients in the metropolitan asylum hospitals, which had been 84, 78, and 72 on the three preceding Saturdays, further declined to 70 at the end of last week; 7 new cases of small-pox were admitted to these hospitals during the week, against 8 in each of the two previous weeks. The Highgate Small-pox Hospital contained 6 patients on Saturday last, no new case having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 290 and 355 in the two preceding weeks, were 347 last week, and were 51 below the corrected weekly average. The causes of 83, or 2.5 per cent., of the deaths in the twenty-eight towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Brighton, Portsmouth, Bristol, Leicester, and three other smaller towns. The proportions of uncertified deaths were largest in Wolverhampton, Bolton, Halifax, and Newcastle-upon-Tyne.

#### HEALTH OF SCOTCH TOWNS.

The annual death-rate in the eight Scotch towns, which in the three preceding weeks had been equal to 19.2, 19.7, and 21.4 per 1000, further rose to 24.3 in the week ending 4th inst.; this rate was 3.0 above the rate that prevailed last week in the twenty-eight English towns. The deaths referred to the principal zymotic diseases in these Scotch towns, which had steadily declined in the five preceding weeks from 117 to 89, further fell last week to 85, and were equal to an average rate of 3.6 per 1000 in the eight towns, which exceeded by 0.6 the rate from the same diseases in the eight English towns. The 24 deaths referred to diphtheria in the eight towns showed a further increase upon recent weekly numbers, and included 7 in Glasgow, 4 in Dundee, and 3 each in Edinburgh, Aberdeen, and Leith. The 20 deaths attributed to diarrhoea, however, showed a decline. The fatal cases of whooping-cough, which had been 18 and 19 in the two previous weeks, were 20 last week, and included no fewer than 15 in Glasgow. The 13 deaths from scarlet fever showed a decline of 3 from the number in the previous week, but included 4 in Glasgow, 4 in Edinburgh, and 2 in Paisley. The deaths referred to "fever" were fewer than in any recent week, 3 being recorded in Glasgow. Both the fatal cases of measles occurred in Dundee. The deaths referred to acute diseases of the lungs in the eight towns, which had been 100, 108, and 113 in the three preceding weeks, further rose to 135 last

week, but only exceeded by one the number in the corresponding week of last year. As many as 116, or more than 20 per cent., of the causes of the deaths registered in these Scotch towns last week were not certified.

#### HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 22.5 in each of the two preceding weeks, declined to 20.4 in the week ending the 4th inst. During the first five weeks of the current quarter the death-rate in the city averaged 21.9, against 19.8 in London and 18.5 in Edinburgh. The 136 deaths in Dublin last week showed a decline of 14 from the number in each of the two previous weeks, and included 7 which were referred to "fever," 5 to diarrhoea, 2 to whooping-cough, and not one either to small-pox, measles, scarlet fever, or diphtheria. Thus the deaths from these principal zymotic diseases, which had been 8 and 13 in the two previous weeks, further rose to 14 last week; they were equal to an annual rate of 2.1 per 1000, the rate from the same diseases last week being equal to 3.0 in London and 3.1 in Edinburgh. The deaths from "fever," which had averaged less than 3 in the four preceding week, rose to 7 last week, and exceeded the number in any week since the beginning of September. The 5 deaths from diarrhoea, corresponded with the number in the previous week, while the 2 from whooping-cough showed a decline of one. The deaths of infants corresponded with the number in the previous week, while those of elderly persons were somewhat more numerous.

### THE SERVICES.

The following members of the Army Medical Department are under orders to embark for Egypt at an early date:—Surgeons-Major T. Comyn, R. Anderson, W. D. Wilson, B. Jazdowski; Surgeons H. M. Reid, H. O. Stuart, W. H. P. Lewis, F. G. Jenckin, F. H. Trehern, W. Dick. Most of the above gentlemen have only recently returned to England after duty in that country.

RIFLE VOLUNTEERS.—2nd Durham: William Robinson, Gent., M.S., M.B., to be Acting Surgeon.

ADMIRALTY.—In accordance with the provisions of Her Majesty's Order in Council of April 1st, 1881, Inspector-General of Hospitals and Fleets John Trail Urquhart Bremner, M.D., has been placed on the Retired List from the 3rd inst.

The following appointments have been made:—Surgeon Thomas D. Popham to the *Impregnable*, vice Barnes; Fleet Surgeon Henry Hadlow to Royal Naval College at the Cape of Good Hope, vice Henry F. Norbury, C.B.; Surgeon William Edward Breton to Royal Naval Hospital, Cape of Good Hope, vice John B. B. Triggs.

### BANQUET TO THE MEDICAL OFFICERS OF THE EGYPTIAN EXPEDITION.

A MEETING of the subscribers to the Invitation Fund was held, by permission, at the Royal College of Physicians on Monday last, the 6th inst., and was numerously attended. Sir William Jenner Bart., presided. The following resolutions were unanimously agreed to:—

1. "That a banquet of welcome be given at the earliest convenient date to all the medical officers who have recently served in the Egyptian Expedition, in recognition of their gallant services."

2. "That the following gentlemen be requested to act as a Dinner Committee, to arrange the details of the banquet, and to report to the General Committee, if it seem desirable—viz., Sir W. Jenner, Bart., Sir James Paget, Bart., the hon. treasurer and the hon. secretary, ex-officio; Mr. Ernest Hart, Chairman of the Dinner Committee; Dr. T. Bridgwater, Dr. Cholmeley, Dr. Andrew Clark, Dr. R. Farquharson, M.P., Sir Joseph Fayrer, Mr. Cooper Forster, Dr. J. G. Glover, Mr. Prescott Hewett, Mr. Joseph Lister, Mr. John Marshall, Dr. W. M. Ord, Dr. R. Quain, and Mr. S. W. Sibley, with power to add to their number."

3. "That Mr. Spencer Wells be requested to act as

honorary treasurer, and Mr. George Eastes, M.B., as the honorary secretary to the banquet.

4. "That Sir W. Jenner, Bart., President of the Royal College of Physicians, be requested to take the chair at the banquet; and that the invitations be issued in his name and that of the committee."

5. "That medical men only take part in the banquet except as guests."

6. "That all the medical officers of the Egyptian Expedition, with any other gentlemen whom the Dinner Committee may consider it desirable to ask, be invited to the banquet."

7. "That the best thanks of this meeting be and are hereby given to Sir W. Jenner, Bart., for the use of this room, and for kindly presiding on the occasion."

At a meeting of the Dinner Committee, held on Wednesday, the 8th instant, it was resolved that the banquet take place on Tuesday, November 21st, at Willis's Rooms, King-street, St. James's. The price of the dinner ticket is 30s. All applications for places at the banquet must be made to Mr. George Eastes, M.B., 69, Connaught-street, Hyde-park, London, W.; and notice is hereby given that "the number of places being necessarily limited, applications will be attended to in the order in which they are received."

## Correspondence.

"Audi alteram partem."

### TESTS FOR ALBUMEN IN THE URINE.

To the Editor of THE LANCET.

SIR,—My paper in your last number was headed "Another New Test for Albumen." I have just now discovered that there is no novelty in the suggestion of picric acid as a test for albumen in the urine. Using Dr. Neale's valuable "Medical Digest" as a means of reference to the various tests which have been employed for the detection of albumen in the urine, although picric acid is not mentioned in the digest except as one of the materials used for adulterating beer, I incidentally came upon a leading article in the *Medical Times and Gazette* (vol. ii., for 1874, p. 366) in which picric or carbazotic acid is mentioned as having been "lately recommended strongly by M. Galippe in the French medical journals, and noticed in the *Edinburgh Medical Journal* for July last" (i.e., 1874). The writer of the article agrees with M. Galippe that this is "one of the best and most reliable tests for albumen in the urine." The only objection to it that he knows of "is the stain given to the fingers by the reagent." But I find that this stain, unlike the yellow stain caused by strong nitric acid, is readily removed by soap and water. The writer ends his article by saying that "none of the common tests" (including picric acid) "are quite satisfactory and that we still lack one which shall be cleanly, portable, cheap, and certain." He appears not to have made sufficient trial of the picric acid test to ascertain its real value; but having experimented with it now upon some hundreds of specimens of urine I claim for it that it possesses all the advantages which the author requires for an entirely trustworthy test. While, therefore, acknowledging M. Galippe's priority in the use of picric acid as a test for albumen in the urine, it is right to point out that my son's experiments, which proved the power of picric acid to coagulate albumen in solution of all its acid compounds, extended over a period of several months and were published in the "Journal of the Chemical Society" in August, 1874; they were, therefore, contemporaneous with, and certainly quite independent of, M. Galippe's observations.

I am, Sir, yours faithfully,  
Savile-row, Nov. 8th, 1882.

GEORGE JOHNSON.

To the Editor of THE LANCET.

SIR,—I do not know that I can agree with Dr. George Johnson in his prediction that a few of the crystals of picric acid, recommended by him in your last week's issue as a test for albumen, will speedily take the place of nitric acid in all urinary test-cases which are made for carrying in the pocket, but I do think that some form or other of solid reagent will be thus employed and perhaps also will find its way beyond the pocket-case.

For some time past I have been giving attention to this subject, feeling that it would be a desideratum to the medical practitioner to have a reliable test for albumen under such a form. Metaphosphoric acid, which is a solid glacial-looking body, is well known to chemists as a very delicate test for albumen, and I remember seeing, a few years back, its solution proposed for clinical use. Instead of the solution, however, a small fragment may be dropped into the urine to be examined. From very extensive trials extending over a couple of years, I can speak of it as an exceedingly sensitive re-agent and have sometimes found it give a decided indication where heat and nitric acid have failed to show any behaviour. Although an excellent test as far as sensitive behaviour goes, yet otherwise it does not possess all the properties that could be desired. The purer kind of glacial acid sold absorbs moisture from the air too freely to be convenient. There is a more impure form, which I am told contains some metaphosphate of soda, which is not so deliquescent, and which may be broken into fragments, and thus kept for use. This, for between the last two and three years, I have carried in my urinary test-case as a companion to my cupric test-pellets for sugar (I observe Dr. Johnson refers to some Cooper and Fehlings' test-pellets, and presume he alludes to the pellets which have been prepared at my instigation and under my directions, by Mr. Cooper, and which I brought to the notice of the profession about three years ago) and have entirely escaped from the inconvenience occasioned by a reagent like nitric acid. The metaphosphoric acid, however, although deliquescent, does not dissolve quickly, and the undissolved part of the fragment remaining after use is apt to cling to the interior of the tube in such a manner as to be quite troublesome to wash out. I have tried mixing the acid with pounded cane-sugar, chloride of sodium, sulphate of soda, and such like, but have not obtained what I could regard as a perfectly satisfactory product. Lately I have looked in another direction, and have alighted upon something which has appeared to me to give promise of yielding what I have been seeking for.

The combination of yellow prussiate of potash and acetic acid has been known of old as a good test for albumen, and I have frequently appealed to it when I have wanted the assistance of corroborative evidence. Now, citric acid may be made to take the place of acetic acid in liberating the ferrocyanic acid, which is the precipitant of the albumen. The combination yields a product which is devoid of any obnoxious properties, and possesses the essential quality of ready solubility in water. Probably it will be found that the best way of using it will be as a compressed pellet—the two substances being deprived of the water of crystallization, that they will yield, and instead of being previously mixed, perhaps compressed, one on the top of the other. These, however, are details which are under consideration.

Since your publication of Dr. Johnson's communication I have tried the picric acid, which, as a test, answers to all that Dr. Johnson has said of it. One objection, however, belonging to it is its deep yellow staining property; and also, its form as a solid agent is not a very satisfactory one to deal with. I have tried the picric acid, and the combination of yellow prussiate of potash and citric acid, against each other, and for delicacy the latter seems quite equal to the former. It remains to be ascertained whether it will serve in all cases of albuminous urine; but, on account of the acid present, it certainly serves in alkaline albuminous urine where Dr. Johnson suggests that picric acid alone might possibly fail.

I am, Sir, your obedient servant,  
Grosvenor-street, Nov. 8th, 1882. F. W. PAY.

To the Editor of THE LANCET.

SIR,—I am a little surprised to see Dr. G. Johnson advocating the use of picric acid as a new test for albumen in the urine, as it was in use in the wards of the Edinburgh Royal Infirmary when I was a student, ten years ago, and its action on albuminous substances has been long known to chemists. I continued to employ it for several years, using a filtered saturated solution of the acid, into which I poured a few drops of urine. But during my term of office as pathologist at the General Hospital I became convinced that it was a less delicate test than Heller's method of using nitric acid in the cold, while that, again, I gave up for boiling and acidulating with acetic acid. It is important, if we wish to succeed with this last test, that the urine should be clear, and, if necessary, it must be filtered; only the upper half

of the column of fluid should be boiled, and then a few drops of dilute acetic acid are added. The tube should be held against a shaded back-ground, when the faintest haze of albumen can be seen.

I have long been aware that the presence of chloride of sodium favours the coagulation of albumen by heat, and I think some advantage may be obtained by adding a little brine or solution of sulphate of magnesia to those urines of low specific gravity in which the discovery of a trace of albumen is often so desirable to confirm suspicions founded upon other abnormal signs. But I am in accordance with the best authorities when I say that we do not want other tests than these for detecting albumen in the urine. It is doubtless true that many proteids are present in it which may be thrown down by the use of various reagents, but albuminuria should be restricted in its significance to the presence in the urine of an albuminous substance coagulable by heat or precipitated by neutralisation.

We shall hardly make much advance in knowledge if, by the use of a variety of reagents, we confound serum albumen and para-globulin, which gave the above reactions, with various peptones and pro-peptones, which seem to find their way into the urine under, at present, little understood conditions.

I am, Sir, yours faithfully,

Birmingham, Nov. 7th, 1882.

ROBERT SAUNDSEY, M.D.

To the Editor of THE LANCET.

SIR,—In the year 1874, when I was endeavouring to find some single reagent which should be reliable as a test for albumen, and which also could be carried with safety in my urinary pocket-case, there appeared in the *Medical Times and Gazette* for Sept. 26th, a notice of the picric acid test, attributed therein to M. Galippe. For many months I carefully tried it, but in the end, failing to get full confidence in its reliability, I put it aside. There are two drawbacks to its use: the first, easily avoided, is that excess of albuminous urine redissolves the precipitate; the other, of much more importance, is that the potassium salts will also make a precipitate with picric acid. It fails, then, as a single test in the same way that heat does; and consequently, although it would be very convenient to be able to avoid the use of nitric acid, I am afraid that picric acid will scarcely take its place.

I am, Sir, yours faithfully,

Gloucester, Nov. 6th, 1882.

RAYNER W. BATTEN.

## THE REPORT OF THE ROYAL COMMISSION ON HOSPITALS.

To the Editor of THE LANCET.

SIR,—It seems important to challenge the conclusion of the Commissioners that "well-conducted" fever hospitals are no danger to their neighbours, and their inference that therefore ill-conducted fever hospitals, like those of the Asylums Board, should be permitted in close proximity to inhabited houses. The danger of small-pox hospitals, so long denied, is now fully recognised; but the Commissioners admit that they have received no evidence as to the spread of disease from fever hospitals, but many assurances to the contrary from hospital authorities. Their opinion, therefore, that fever hospitals are harmless is avowedly based on a hearing of one side only of the case. It is not difficult to understand why the opposing evidence did not happen to be submitted. The Commission sat with closed doors; no one knew what statements had been made to them, and, unless they called for evidence on any particular point impugning the management of hospitals, no one was likely to volunteer it except those persons who had suffered from such mismanagement.

Now of all the populations surrounding the hospitals of the Asylums Board only those of Hampstead and Fulham have had the means and energy thoroughly to investigate the facts; but as the Hampstead and Fulham Hospitals had never been used for fever cases, and as the only official examination into the spread of disease from the hospitals of the Asylums Board (that made by Mr. W. H. Power) was confined to small-pox epidemics, the facts as regards fever hospitals have not received the same searching examination.

A few years ago the Royal Commission, had it then existed, would probably have given equally comforting but equally misleading assurances about small-pox hospitals,

and as upon one very important question as regards fever patients—viz., the possibility of conveying them long distances—the Commissioners' conclusions are at variance with well-ascertained facts, a doubt necessarily arises as to the soundness of their conclusions on this the less considered portion of their inquiry. For years past the stock answer of the Asylums Board to all suggestions that small-pox hospitals should be placed far afield was that it had been informed by some high but unnamed authority that patients could not safely be moved more than three miles. This is now admitted to be untrue as regards small-pox, but the old turnip and sheet are still made to do service as "bogie" in the interests of those who desire to retain the Board hospitals and use them for fever in their present unisolated positions. Now, it so happens that this very point was thoroughly investigated years ago by no less an authority on fever than the late Dr. Charles Murchison, as the readers of his work on the "Continued Fevers of Great Britain" will remember, for he found on carefully comparing the mortality amongst patients in the London Fever Hospital brought in from its immediate neighbourhood, with that of patients of the same age and condition brought from places many miles distant, that the additional distance travelled produced no ill effect. If therefore the supposed difficulty of removing fever patients be the only ground for retaining fever hospitals in crowded neighbourhoods, where, unless their rules be observed with a strictness never yet secured, danger must be created, the distant and well-isolated hospitals now at last recommended for small-pox should obviously be made available for all kinds of infectious or contagious diseases. Well-conducted fever hospitals, as has been before pointed out, are perhaps as harmless to their neighbours as well-conducted powder mills; but because rules, however stringent, are, as everybody knows, daily and hourly violated, fever hospitals, like powder mills, should be placed where the public will be safe, not only when the rules are observed, but when they are disregarded. What rule can have more authority than an Act of Parliament? yet the very existence of small-pox hospitals is due to the fact that the Compulsory Vaccination Acts are so often disobeyed.—I am, Sir, your obedient servant,

Belsize-park, Oct. 23rd, 1882.

PEARSON HILL.

## "A SIMPLE OPERATION FOR VARICOCELE.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Oct. 28th there is a letter from Dr. Campbell Black, which contains some would-be severe strictures upon the mode I used in treating the silk employed in tying the veins in a simple operation for varicocele. Dr. Campbell Black seems to be fully alive to the immense strides which have during the last few years been made in the scientific treatment of surgical diseases by the introduction and application of the germ theory of putrefaction and its prevention to the conduction of surgical operations.

How astonished would the earlier contemporaries of John Hunter have been had anyone attempted to supersede their clumsy and painful arrangement of wire and interposed cork for the occlusion of vessels, by a carbolised catgut or asepticised silk ligature, cut short and left in the wound. In the present day, however, provided any possible germs in the material be first rendered inert by subjection to a boiling temperature in a germicide solution, and provided that afterwards the material be kept from further germ contact by immersion in the same solution until the moment it is used, one has no hesitation in leaving it in the wound. One can easily understand how, as Dr. Campbell Black observes, such precautions, which ought in the present state of our knowledge to be used by every thinking surgeon, would some few years ago have been regarded as "fetish worship." This is not surprising, however, when we reflect that it is less than a century ago that the operator who tightly ligatured an artery would, had death ensued, have been considered guilty of manslaughter.

Dr. Campbell Black describes a knot which he uses in his varicocele operations as a "reef" knot, and he afterwards goes on to say that it "can be tightened as frequently as necessary by tension of the free ends." Evidently in his anxiety to criticise he has become hazy as to the difference between a "graamy" and a "reef," as of course no reef knot could, when once tied, be made tighter by any amount of tension.

I am, Sir, yours faithfully,

York, Oct. 31st, 1882.

W. H. JALLAND.

## "ON ABSORBENT DRESSINGS, ETC."

To the Editor of THE LANCET.

SIR,—Permit me through you to thank Mr. Berry for his courteous notice of my letter of the 28th ult. As my letter referred to his paper in your issue of Oct. 21st, after much thinking I see no occasion to withdraw a single statement—each was a fact or else an accurate deduction. The premises may have been false.

In his letter of Nov. 4th, Mr. Berry gives a somewhat different account of Case 1 to what appeared in his original paper. In the same letter it appears that Mr. Berry regards erysipelas as a local contagious disorder. I am ever ready to admit my faults, but even yet I must look upon erysipelas as a general infectious disease, accompanied by fever and a local manifestation in the form of a rash, which (of course) does not necessarily appear where the germs gained access into the system. Of course it may. I need not discuss its pathology; better men than I have done so already.

Next, Mr. Berry proceeds and misquotes me, leaving out an important word. Nor did I impute death (in the fatal case) to the dressing; I merely introduced the case as not having been reported in the original paper. I freely admit the existence of a *vis medicatrix naturæ*, also there is not to be forgotten the *vis maligna*.

With regard to case 4, I think Mr. Berry admits to himself that I was right. He endeavours to find fault with my logic, but fails. Because he gets confused he gives a positive meaning to "learn (?)," which has a sign after it indicating doubt. Mr. Berry seems, from his letter and his paper taken together, to consider that "abundance of carbolic spray and lotion" constitutes the antiseptic system of Lister. This is a fatal error. Gamaliel was not a surgeon.

Finally, are we to lay aside the modern antiseptic (not the abortive or modified Wigan) system which has been followed by the best results in hundreds of cases for the sake of four cases treated in some other way, two of which did best where some attempt at antiseptic treatment (accidentally in one case, as Mr. Berry admits) had been employed?—I am, Sir, yours truly,

Brighton, Nov. 4th, 1882.

H. ROGERS-TILLSTONE, M.B.

## MANCHESTER.

(From our own Correspondent.)

MANCHESTER is justly elated this week at finding itself an *alma mater*. This city opened its arms to receive the Gown, on Wednesday last, in our noble Town Hall. The occasion was the conferring of degrees by Principal Greenwood; and among the associates who were entitled to receive that honour at his hands were fourteen members of the medical profession.

The worthy Principal of Owens College, clad in red raiment, supported on either side by the Archbishop of York and the Bishop of Manchester, gave us an address in which, after a sympathetic allusion to the private sorrow that had caused the absence of the Chancellor, the Duke of Devonshire, he told us that almost exactly 240 years ago a petition was presented to Parliament urging the necessity of a university in the North of England. In answer to various critics, one of whom "foresaw that Pegasus was about to be yoked to a cotton mill," he reminded us that the "orators and historians of Athens were wont to boast that their city was at once the mart of the world and the school of Greece, the most favoured seat of commerce, and the chosen home of art and letters, of eloquence and philosophy."

On the previous Friday we had the annual dinner of the Medico-Ethical Society, which, thanks to the able superintendence of the stewards, Messrs. Ewart and Dacre Fox, and the culinary resources of the Queen's Hotel, passed off most creditably. There were about fifty members and visitors present, and after the usual loyal and patriotic toasts had been duly honoured, the President of the Society, Mr. Hardie, rose to introduce the toast of the evening, "The Medico-Ethical Society, coupled with the name of Dr. Stone, the oldest member present." The President showed us that this excellent institution has done much for ethics, and is the parent of all similar societies in the kingdom, and that

its tariff of fees has been largely copied by them without any acknowledgment.

Owing to the resignation of Mr. Lund through ill-health, Mr. Hardie has been appointed Surgeon to the Royal Infirmary. For the assistant-surgeonship thus left vacant there are three candidates:—Mr. Wright, Mr. Howlett, and Mr. Young. Mr. Wright is B.A. and M.B. Oxon., a Fellow of the College of Surgeons, Surgeon to the Children's Hospital, and Surgical Registrar to the Infirmary. Mr. Howlett was recently Resident Surgical Officer to the Infirmary, and is a Fellow of the College. Mr. Young is also a Fellow of the College, Pathologist to the Infirmary, and Surgeon to the Throat Hospital. The contest promises to be a keen one.

Nov. 6th, 1882.

## EDINBURGH.

(From our own Correspondent.)

THE number of students who have so far matriculated is, I understand, some 300 more than at the corresponding period of last year. Whether the chief increase is in the faculty of medicine is not yet known. All the University medical classes are very large, some of them larger than they have ever been before. Professor Chiene must have at least 400 students, for he has been obliged to leave his own class-room for the Anatomy theatre, but it is not at all too large. The extra-academical classes, on the other hand, are as a rule very small, Dr. John Duncan's being, so far as I have been able to ascertain, considerably larger than any of the others.

On Saturday afternoon Lord Rosebery delivered his rectorial address to the students of the University, in the United Presbyterian Synod Hall. It is probable that between 2000 and 3000 students were present, and the preliminary proceedings were riotous to a degree. Fully an hour before the time appointed for the delivery of the address the students began to assemble in front of the hall, and, while waiting for the doors to be opened, peas were freely thrown about, and the glass of one of the large lamps at the entrance-gate was broken. About the same time the new Professor of Greek drove up in a cab, and was cordially cheered. Evidently not aware that the gate was still closed, Professor Butcher made his way towards it. No sooner had he got within sight of the door than the cry was raised, "Let's give him a squeeze." This suggestion was at once acted upon, and attempts were made to knock off the professor's hat with walking-sticks. The professor, whose coat was torn in the scuffle, took his rough reception with great good-humour and eventually was able to shake himself clear of the crowd. After the doors were opened the galleries and body of the hall were speedily filled, and the same disorderly proceedings were indulged in. Soon after two o'clock the Lord Rector, the Chancellor, the Principal and Professors of the University and other officials ascended the platform, but the same riotous proceedings continued. While the introductory prayer was being delivered by Professor Flint, great and unseemly uproar prevailed. Repeated cries of order from the platform failed to produce any effect on the students. Professor Kirkpatrick then proceeded to present to the Chancellor the nobleman and gentlemen recommended for the degree of LL.D., but he fared no better at the hands of the students; the remarks he made being, in consequence of this continued uproar, entirely inaudible to any save the Chancellor and the gentlemen receiving the degrees. Indeed, it was not until the Lord Rector proceeded to deliver his address that quiet was at length obtained. After thanking the students for his election, Lord Rosebery paid a graceful tribute to his predecessor, the late Sir Robert Christison, and said, "In this place, where you all knew him, it is unnecessary to speak to you of Sir Robert Christison, nor am I competent to pay a tribute which should be worthy of his fame. What I can speak of him from personal knowledge was his unwearied energy, his faithful performance of public duty, and his rare devotion to this University." The general subject of the address was patriotism, especially as applied to Scotchmen and Scotch students. Lord Rosebery commended to the students the cultivation of national sentiment. He was careful to say that of Scotch character he did not mean peculiarities of custom or accent.

It was not by "the mere utterances of time-honoured shibboleths, nor by constituting the plaid a wedding garment, without which none is welcome," that Scotland was made; nor by these means would Scotland be maintained. The address, which was at the same time both eminently eloquent and practical, was listened to with great attention, the most striking passages being loudly applauded. After the delivery of the address the same uproar which characterised the commencement of the proceedings prevailed.

### GLASGOW.

(From our own Correspondent.)

THE appointments in connexion with our Sick Children's Hospital have been made public. They are as follows:—Physicians: Professor Leishman, Dr. J. Findlayson, and Dr. S. Gemmell (extra physician); Surgeons: Dr. H. C. Cameron, Dr. Wm. McEwen, and Dr. W. J. Fleming (extra surgeon); Pathologist: Dr. Joseph Coats; Oculist: Dr. Thos. Reid; Aurist: Dr. Thomas Barr; Dentist: Mr. Rees Price. With the exception of Mr. Price, all these gentlemen already hold other hospital appointments. The hospital is now on the eve of completion, and will probably be opened before the close of the year.

The Faculty of Physicians and Surgeons has resolved to institute a qualification in State Medicine, to be granted only to men already having a licence to practise. The nature and extent of the curriculum required, and of the examination, have not yet been determined.

The Faculty has now seriously taken alarm at the evident effect produced on the public mind by the report, somewhat adverse in its references to the Faculty, which has been furnished by the Royal Commission on the Medical Acts. Notwithstanding the very favourable notice of the Faculty's examination by the visitors sent down by the General Medical Council, it is recognised that the mind of the profession across the border is still hostile to this particular Corporation. A committee of the Faculty has therefore been appointed to consider these reports and the evidence on which they are based; though it is not yet clear what public action it may take with the view of refuting the charges brought against it, and of bringing its true standing and practice properly before the profession and the country at large. It is strongly felt here that the Faculty has been grossly maligned, and its procedure in regard to examinations misrepresented. It has for centuries rendered incalculable service to the profession in the West of Scotland, through its magnificent library, the general care it has taken of medical interests, and the encouragement it has always given to scientific study and work by its consistent and liberal recognition of extra-mural teaching. Its downfall would be felt as a calamity in this part of the country.

Our medical schools are again in full swing. At the University the session was opened by a characteristic and enjoyable address by Professor Gairdner, in which the past and present systems of medical education were ably reviewed, and reference was made to the immense progress made, especially in diagnosis, of late years.<sup>1</sup>

The commencement of the session at the Royal Infirmary School of Medicine was marked by a little extra ceremony and importance, as the new school buildings are now in use for the first time. The speeches were delivered, one by the Lord Provost of Glasgow, and one by Dr. Eben. Watson. The Lord Provost showed his usual familiarity with medical and public health matters, and expressed his regret that among the classes conducted at the infirmary, no room had been found for a course on hygiene. He frankly admitted, however, that neither the town nor the county authorities have shown by the salaries they give to their health officers, that they estimate at their true value the services rendered by these gentlemen; and so it is probably too much to expect that the medical profession, which gives of its services so much gratuitously already, should be very forward in making a new departure in the direction indicated. Dr. Watson's address was given with the eloquence and point of which he is admitted to be so complete a master.

The conversazione which took place at the inauguration of the new buildings for the Infirmary Medical School, was

a most brilliant affair. There was a little good music, but no speeches, beyond a few introductory remarks by Dr. Wm. McEwen; Messrs. Hilliard showed a number of medical, surgical, and obstetrical instruments; various druggists exhibited whatever was new in the way of pharmacy; Drs. Fleming and Newman gave demonstrations of the most recent novelties in physiological and pathological research; while the commissariat arrangements gave the greatest satisfaction to everybody, including the students. Probably it was the facilities provided for anatomical studies that attracted most attention, especially the "osteology" room—why not bone-room? The elder practitioners (of whom and of students there were over 300 present) were unanimous in saying that they enjoyed no such advantages in their student days.

The effect produced on many present by all this display was striking. Some did not hesitate to assert that the rival school, the Andersonian College, was completely left behind, so far as thorough equipment can be said to make or mar a school; and that if it intended to maintain its position in the field it would need to put forth a very mighty effort. It does seem as if that school had missed its day of grace in failing to amalgamate with the Royal Infirmary School.

Perhaps the ablest, certainly the bitterest, of all the introductory lectures given during the last few days was that of Mr. D. C. M'Vial, at the opening of the Western Medical School. It took the form of a history of medical education in intra-mural and extra-mural schools, but its substance and culmination were a fierce attack on Glasgow University, for its alleged illiberal conduct in, till very recently, refusing to recognise intra-mural lecturers, and thus endeavouring to establish and maintain for itself a strict monopoly of medical teaching in the West of Scotland.

At the Andersonian College the medical session was opened by a very interesting address by Dr. James Christie.

### SCOTTISH NOTES.

(From our own Correspondent.)

PROFESSOR HAMILTON, in his inaugural address to the pathology class at Aberdeen, delivered on Nov. 1st, gave a history of the endowment of the chair by Sir Erasmus Wilson, whose life he sketched; he showed how the intimacy between Professor Pirrie and the generous donor had led to the worthy gift of £10,000 to his father's *alma mater*, and afterwards proceeded to point out the objects in view and the subject to be taught by him. After a rapid survey of the history of his subject, he showed how from the "theory of medicine" pathology had come to be considered as the "science of medicine"; how, based upon a thorough knowledge of histology and physiology, the end in view was to ascertain the *causes* of disease. As illustrating what had in recent years been done in this direction, the lecturer referred to the success met with in determining the etiology of zymotic diseases, while the manner in which many skin affections were associated with constitutional disorders was still a matter of surmise only. Pathology at the present time resolved itself into—1st, minute anatomy; 2nd, experimental investigation; and, 3rd, the comparative study of diseases in the lower animals. The first of these was the basis of all therapeutical deduction, and when thoroughly acquired can be put in constant use at the bedside, and is easily carried about. It was his determination that, as far as possible, the subject should be taught practically, the only sound and useful method of teaching pathology. He wished to discourage all supercilious dilettantism, and reach forward with a determined purpose, "Heart within and God o'erhead."

Professor Stirling in his introductory lecture to the physiology class, after referring to the recent changes in the Aberdeen University, went on to consider the connexion existing between physiology and other departments of medical study, and finally to urge its importance in relation to our every-day life. Dr. Stirling spoke of the importance of considering the relationship between man and the lower animals, and illustrated, by reference to the work of Pasteur and of Koch, the advantage to animals as well as men of experimental inquiry. Proceeding to push the comparison further, the studies of Sir John Lubbock and Dr. Romanes were invoked as hopeful evidence that psychology might also be

<sup>1</sup> This address will appear in our next impression.—ED. L.

advanced by comparative study. The whole question of mind in the lower animals bears intimately upon the "Theory of Descent," and a question at present before evolutionists is, Is the mind of man distinct from that of the lower animals, or has it been evolved from the "mind" of the lower animals? Mr. Wallace answers the first question, and Mr. Darwin the second, affirmatively. The study of infant psychology is here of great interest and importance, and Mr. Darwin was amongst the first to examine the question. Recently Professor Preyer of Jena has published an elaborate work detailing in the most minute manner very numerous observations made regarding the mental development of his own child, and showing the vast influence of heredity. He is clearly of opinion that the intelligence of a child—even before it can speak a word—is ahead of the most intelligent animal. While the anatomical resemblance between man and the higher apes is of great interest, this question of mental evolution must have much study in the future, and the answer will be assisted by regard to the various degenerations to which the mind is liable. After showing the further connexion between physiology and other medical studies, Professor Stirling concluded an eloquent address by urging the importance of teaching physiology in schools, and to the young people generally, and more especially to girls. Quoting M. Paul Bert, he said: "When you educate a boy, you, perhaps, educate a man; when you educate a girl, you are laying the foundation for the education of a family."

After so recently having had the pleasure of directing the attention of your readers to Dr. Struthers' efforts to obtain the foundation of bursaries for the students at Aberdeen it is very satisfactory to record what has already been done in response to the appeal. At the meeting of the Senatus held last Saturday it was intimated that George Thompson, Esq., of Pitmiddden, had offered the sum of £6000 to be applied in the foundation of medical bursaries. It was resolved cordially to accept the gift, to record best thanks to the donor, and to send him a copy of the minutes. Mr. Thompson has shown great liberality, alike in the amount of money given and in the manner in which it is offered to the Senatus, that body being allowed full discretion as to the particular way in which the object stated shall be served. The Senatus will not be placed in any difficulty by this handsome bequest, as there are very numerous needs to be supplied, and it is certain that the fullest good will be done with the money by those having the best knowledge of the wants of the university. Added to the recent grant by Mr. Marr, this sum will form an excellent nucleus, and ere long Aberdeen may be enabled to offer the same attractions to medical students which have so long proved useful in the other Faculties. Only a few weeks ago Mr. Thompson gave £4000 to local charities.

The students at Aberdeen have petitioned the Senatus against having pathology embraced as a compulsory subject in their curriculum. Students joining now and hereafter will of course do so knowing that subject to be compulsory, but there is something to be said for those who feel that the new chair was not embraced in the course when commenced by them. Even though optional to present students, the majority will probably find it advantageous to take Professor Hamilton's class.

At a recent meeting of the Perth Water Commissioners a resolution somewhat to the following effect was carried by a majority: "That an opinion of counsel should be taken as to whether some recent statements by Dr. Trotter are libellous, and if competent, that an action should be raised against that gentleman." It appears that the gentleman referred to, feeling that the typhoid fever now and frequently prevalent in Perth is due to the admixture of sewage with the water-supply—an opinion shared by the profession in that city—has expressed himself very strongly on the subject.

## IRELAND.

(From our own Correspondent.)

DISSECTING by gaslight has been found to be unsatisfactory, and in consequence the Board of the Ledwich School of Medicine have made arrangements to have introduced into their dissecting-room one or more electric lamps. I believe the result will answer all expectations; and there is no doubt but that the good example shown by this school,

the largest in Dublin, will conduce to its prosperity and to the advantage of the students at the institution.

The annual elections for the Council of the Surgical Society of Ireland took place last Monday in the College of Surgeons. No votes were recorded except by members of the Society, who were either Fellows of the College of Physicians or Surgeons. The only change was the addition of Mr. Kendal Franks of the Adelaide Hospital, who replaced a member of Council, who has been elected a vice-president of the College.

Collections in aid of Hospital Sunday will take place on Sunday next, the 12th inst., when upwards of 200 churches will join in the movement. It has been usual for the past few years for a football match to be held the Saturday previous, and the sum obtained, generally upwards of £40, after all expenses have been paid, is handed over to the Hospital Fund. This year the fifth annual match will take place on the 11th inst., when one of the finest contests of the season will be played by teams representing the County Dublin, and the United Hospitals.

A slight increase in small-pox appears to have taken place in Belfast during the last week, eight fresh cases having been admitted to hospital, making a total of fourteen under treatment.

It is intended by the students of Mercer's Hospital to present an address to Dr. George F. Duffey, who recently resigned the post of physician to that institution.

Dr. Atthill, master of the Rotunda Lying-in Hospital, will vacate his post this month, after a seven years' tenure of office. The name of Dr. Macan, ex-assistant-physician, has been mentioned as a probable successor. The appointment is a very important and lucrative one, and is in the hands of the governors.

In the report of the Reformatory and Industrial Schools in Ireland for the past year it is remarked that a very large majority of the deaths in 1881, in industrial schools, was from scrofula and tuberculosis in their various forms. Von Niemeyer states that one of the primary causes of scrofula amongst children is the coarse diet to which they have been accustomed before admission into reformatory and industrial schools. Such food, containing little nutriment in comparison to its bulk, is insufficiently assimilated by their tender stomachs. The normal functions are thus checked, and an impoverished and vitiated circulation is created, which renders them peculiarly susceptible to receive and nourish the germs of tuberculosis that float in an atmosphere vitiated by the breath of consumptive children. It has been observed that peat bogs check, in a marked degree, the development of consumption. In 1854 the Directors of Convict Prisons found the prisoners in Spike Island, Cork, dying in numbers from consumption and other scrofulous diseases, the mortality in that year being 289 out of a total of 3701 inmates of convict prisons. The directors established an invalid dépôt at Philipstown, which is situated on a gravel bank in the midst of a bog. The deaths were reduced in the following year to 149 in a total prison population of 3147, and in 1856 the number of deaths fell to 54. The Philipstown Reformatory, with an average of 290 inmates, on the site of the above-mentioned convict dépôt, enjoys an almost perfect immunity from the disease. There was no death in it during 1881, and only one from consumption in the two previous years. In the Glencree Reformatory, also situated on a bog, with an average of 276 inmates, there has not been a single death from tubercular diseases during the past three years. On the other hand, in the Upton Reformatory, with an average of 243 inmates, there were 5 deaths from consumption last year, 2 in 1880, and 3 in 1879.

## PARIS.

(From our Paris Correspondent.)

THE diagnosis of syphilides is not at all times an easy matter, and any contribution to the literature of the subject will always be acceptable. Dr. Mauriac, Physician to the Hôpital du Midi, the well-known hospital for venereal affections in the male, delivered a very interesting lecture on the subject which may be summarised as follows: In giving a description of the topography of syphilides, Dr. Mauriac observed that their distribution on the different regions of the body presents certain peculiarities which are not found

in other affections of the skin. Erythematous syphilide is found principally on the trunk and flanks, on the inner parts of the limbs and on the flexor more than on the extensor aspect. The papular form has its seat of predilection on the face, the ala of the nose, and on the forehead at the roots of the hair, the upper part of the neck, the trunk and on the limbs in all directions. The scaly forms, with all their varieties, invade principally the palms of the hands and the soles of the feet. Pustular syphilides, superficial and impetiginous, affect the scalp, the beard and, in general, the regions covered with hair. Ecthyma and rupia attack by preference the limbs, principally the lower limbs. As for tubercular eruptions, they are disseminated all over the body. Thus it may be seen that syphilitic eruptions may affect the entire cutaneous covering of the body. There are, however, some parts of it which would seem to form exceptions to this rule, such as, for instance, the clavicular and sternal regions, where simple and parasitic eruptions are so common. The same may be said of the back of the hand, and this remark is particularly applicable to the exanthemata. Papulo-squamous eruptions are never seen on the limbs on the extensor surface, at least systematically, as is the case with one of the most common and most typical of non-syphilitic eruptions, psoriasis. The natural orifices, the commissures of the lips, isthmus of the fauces, orifices of the nostrils, the vulva, and anus, are the seat of predilection of the earlier syphilitic eruptions, and, among others, mucous patches are there particularly noticed. The circular forms of simple erythema may be found on all parts of the body; whereas the same forms of erythematopapulous syphilides affect by preference the chin, the cheeks, forehead, the neighbourhood of the anterior and internal parts of the limbs and the buttocks. The syphilides appearing later and affecting the tissues deeply are generally situated on the nose, lips, scalp, the sternal and clavicular regions, the buttocks, and more frequently on the legs near the joints than on the thighs.

Madame Madeleine Brès, one of the few French ladies who have become doctresses of the Faculty of Medicine of Paris (for I may say *en passant* that French ladies in general are not at all partial to the study and practice of medicine), has submitted a paper, through M. Wurtz, to the Academy of Sciences on an analysis of the milk of the Galibis women, the savages referred to in my letter to THE LANCET of Aug. 12th last. Both the women from whom the milk was taken are multiparæ. One is suckling her sixth child, three months old; the other her seventh, two years old, and in which dentition is complete. The following is the result of the analysis obtained from a kilogramme of milk:—

	A.	B.
Butter .....	34.70	51.96
Casein .....	9.54	13.12
Lactose .....	74.78	77.70

The analysis was performed according to the method adopted by Dr. Adam, and shows that the two samples of milk were rich in butter and lactose, whilst the proportion of casein was, on the contrary, extremely feeble, thereby approaching more to the composition of cow's milk. It may be interesting to give the analysis by MM. Bouchardat and Quevenne of the milk of women in general:—

Heat-forming substances—Butter.....	20.73
Lactine and extractive matter .....	74.20
Plastic substances—Casein.....	13.68

Although the winter session is supposed to begin on October 15th, the doors of the Faculty are not opened for the courses before the first week of November. The following is a list of the Professors who are to lecture during the session:—Prof. Gavarret, Medical Physics; M. Gariel, General Physics; Prof. Jaccoud, Medical Pathology; Prof. Sappey, Anatomy; Prof. Bouchard, Pathology and General Therapeutics; Prof. Wurtz, Medical Chemistry; Prof. Duplay, Surgical Pathology; Prof. Le Fort, Practical Surgery; Prof. Robin, Histology; Prof. Cornil, Pathological Anatomy; Prof. Laboulbène, History of Medicine and Surgery; Prof. Brouardel, Forensic Medicine; Profs. Germain Sée, at the Hôtel Dieu; Lasègue, La Pitié; Hardy, La Charité; Potain, Hôpital Necker, Clinical Medicine; Prof. Ball, at the Sainte-Anne Asylum, Clinical Pathology of the Mind and Brain; Prof. Parrot, Hospice des Enfants Assistés, Diseases of Children; Prof. Fournier, Hôpital Saint Louis, Syphilitic and Cutaneous Affections; Prof. Charcot, La Charité, Diseases of the Nervous System; Profs. Gosselin, La Charité; Richet, Hôtel Dieu; Ver-

neuil, La Pitié; Trélat, Hôpital Necker, Clinical Surgery; Prof. Panas, Clinical Ophthalmology; Prof. Depaul, Clinical Midwifery.

In addition to the above, supplementary courses are given by *agrégés* of the Faculty on the various branches of medical science. There are also a number of free professors who give lectures, and whose instruction is officially recognised.

The typhoid epidemic in Paris may now be considered fairly on the decline, as, according to the mortuary report of last week, the mortality from that affection has declined from 173 of the preceding week to 125. The number of cases in town and the admissions into the hospitals have also considerably diminished, and during the last three or four days no fresh cases have been reported. The number of deaths from all causes in town and in the hospitals amounted to 995, that of the preceding week being 1077. The number of births recorded for last week was 977, and marriages 467.

Nov. 7th, 1882.

## MEDICAL NOTES IN PARLIAMENT.

### *Scarlatina at Arklow.*

In the House of Commons on Thursday, Nov. 2nd, the Chief Secretary for Ireland answered a second series of questions by Mr. Corbet on the subject of an outbreak of scarlatina in the constabulary barracks at Arklow. The medical attendant ordered the removal of the children affected with the disease into the hospital, and the others went into lodgings with their parents in the town. The sub-inspector was not aware that there was any "consternation" in the town in consequence. It was not 11 o'clock at night, but 9, when the children were removed. The inspector found fault with the head-constable for inviting the men to express want of confidence in the medical officer, but there was no formal censure. The head-constable's removal was wholly unconnected with the question of medical attendance. There was no stoppage from the men's pay on account of medical attendance.

### *The Vaccination Acts.*

Mr. Hopwood asked the Home Secretary if his attention had been called to a case of distraint under the Vaccination Acts, at Bedford, in which, for a fine of 11s. 6d. laid on March 13th, 1882, goods had been seized of the value of eleven guineas, on Sept. 6th, 1882, six months after the case was heard, and while the parents were mourning for the loss by death of the child for the non-vaccination of which the prosecution was instituted; and if he would make such representations to magistrates, or issue such instructions, as would prevent in future similar proceedings.—Sir W. Harcourt said he had no official information of the case. He must point out that he had no power to set aside the distraint, and when the hon. member talked about issuing instructions to magistrates which would prevent them putting the law in operation, he must say he had often stated in the House that he had no power to direct anything of the kind. If the law was put into execution in a harsh manner, the Secretary of State had, under limited conditions, power to interfere with the sentence, but he had no power to interfere with judicial functions.

On Monday, on the motion of Mr. Dodson, a copy was presented of a memorandum by the medical officer of the Local Government Board, on the probable origin of erysipelas at the Norwich public vaccination station in June 1882.

### *The Murder of Dr. Maclean.*

Sir C. Dilke stated to Dr. Cameron that Her Majesty's representative at Santiago was instructed to press upon the Chilean Government the claim of the relatives of Dr. Maclean, late physician to the British Legation, for compensation for his murder by Chilean soldiery in January last.

### *Bristol Sanitation.*

Mr. MacIver asked the President of the Local Government Board if his attention had been called to the action of the sanitary authority at Bristol in summoning the owners (chiefly working men) of seventy-four houses condemned by the medical officer of health, these houses having been erected on the strength of the official sanction of the plans; and, whether such proceedings, without compensation to the owners of the property, were approved by the Board.—Mr.

ison replied that the medical officer of health reported a number of houses as being unfit for human habitation, because they were built on low lands, which were liable to be flooded whenever there was an excess of rain. It was the plan was approved by the sanitary authority as in accordance with their by-laws, but the approval referred to the construction of the buildings, and not to the sites. The Local Government Board had no control over the sanitary authority in the matter, but the case must be brought before the justices, and it would be necessary to satisfy the justices of the unfitness of the houses for habitation before they could be closed.

#### *Importation of Drugs into Japan.*

In answer to Mr. Alderman Fowler, Sir C. Dilke said he was not aware there was any recent interference with the importation of drugs and chemicals other than medicinal. There were restrictions imposed by Japanese law on the sale of bad and spurious drugs, and such articles had to be submitted to the examination of a Board of Health before they could be sold. There were complaints in 1879 at certain drugs were unfairly condemned, but none had been made since that time.

#### *Queen's Cadetships.*

Dr. Lyons asked the Secretary of State for War, if, under existing regulations, the sons of medical officers of the army were ineligible for nomination to honorary Queen's cadetships; and, if he would take steps to remedy this inequality in the position of the Medical Department which was felt as a slight to those who risk their lives in the service of the State.—Mr. Childers reminded his hon. friend that Queen's cadetships were open to the sons of medical officers. As to Queen's honorary cadetships, the arrangements were under consideration; but he could give no assurance that he could amend the system, which was a delicate one to alter.

#### *Surgeon Wheeler and the Irish Government.*

Mr. Gibson asked the Chief Secretary to the Lord Lieutenant of Ireland whether Surgeon William Ireland Wheeler, Vice-President of the Royal College of Surgeons, at the request of the Irish Government, attended Mr. Carter, who was, in the month of March last, fired at and dangerously wounded in the county of Mayo; whether Surgeon Wheeler attended many visits to Mr. Carter in Mayo, leaving his large practice in Dublin for the purpose, and reported the result of each visit to the Irish Government, and whether Surgeon Wheeler actually furnished his account for such attendance to the Irish Government, and had not been paid.—Mr. Trevelyan replied that Mr. Morony, resident magistrate, reported to Mr. Burke, the late Under Secretary, that Mr. Carter expressed a wish to have the professional aid of Mr. Wheeler, who had previously attended him. Mr. Burke thereupon intimated to Mr. Wheeler that if he visited Mr. Carter, and if that gentleman was unable to pay his fees he must submit a claim for the consideration of the Government. Mr. Wheeler paid many visits to Mr. Carter, and reported the result of each visit to Mr. Burke. He had since furnished an account to the Government for £1147 18s. for his services, and for fees of fifty and twenty-five guineas for two assistants who accompanied him. Mr. Carter stated he was unable to pay the account, and had made a claim for compensation for his injuries. Pending the result of the claim, the Government could come to no decision on Mr. Wheeler's demand. Mr. Gibson gave notice that he would ask that the correspondence between the Irish Government and Mr. Wheeler be laid on the table.—Mr. Healy said he would ask whether there was any record at Dublin Castle of eminent surgeons being sent by the Government to attend persons wounded by the police.—In reply to another question by Mr. Biggar, Mr. Trevelyan promised that the Irish Local Government Board would make inquiries into the alleged ill-treatment of a pauper lunatic woman named Malcolmson, who had been removed from Bothwell in Scotland to Downpatrick in Ireland.

#### *Militia Surgeons.*

A petition was presented from the North of England Branch of the Medical Association for redress of the grievances of militia surgeons.

#### *Regimental Surgeons.*

On Thursday, Sir H. Fletcher asked the Secretary of State for War if he would consider the advisability of reverting to the old system of appointing regimental surgeons and

assistant-surgeons to every regiment in her Majesty's forces.—Mr. Childers reminded the honourable member that the present arrangement of the medical service, which was commonly called the general, as opposed to the regimental system, was finally decided upon by the late Government when Lord Cranbrook was Secretary of State, as recently as 1878. Lord Cranbrook's final words were, "The regimental system has gone, and it will be impossible to recall it." If the present system should appear to be faulty, he (Mr. Childers) should have no hesitation in reforming it, but at the present moment he had no intention of reverting to an arrangement which had been so recently condemned.

#### *Dr. Wheeler's Claim.*

Mr. Trevelyan, in reply to Mr. Gibson, repeated his former statement as to the postponement of the consideration of Surgeon Wheeler's claim; and in reply to Mr. Healy, said there were instances during the last two or three years in which eminent surgeons had been employed to attend upon persons in indigent circumstances, injured either by the police or agrarian offenders, and the fees had been paid out of the law charges.

#### *Lunatics in Workhouses.*

Mr. W. Corbet asked the President of the Local Government Board if his attention had been called to the evils arising from overcrowding in the lunatic wards of workhouses, especially at St. Pancras and at the Dudley Union Workhouse; whether with reference to the latter he had noticed the following passage in the last report of the Commissioners in Lunacy, pp. 159-160:—"Attention has been drawn by the Visiting Commissioners for several years past to the overcrowding of the lunatic wards, but it continues to be as great as ever, and nothing has been done, nor as far as I can learn is anything in immediate contemplation with a view to remove or abate the evil which in the male lunatic ward day-room is indeed becoming worse every year;" whether he had noticed the following extraordinary statement of the Commissioners:—"In the dormitories of this ward also the beds are so close that they touch each other at the sides, and the patients have to climb into and out of their beds over the bottom," with other observations of a painful character; and whether he would take immediate steps to remedy the evils complained of.—Mr. Dodson said attention had been called to the evils referred to at St. Pancras and Dudley. The guardians of St. Pancras had during the present session obtained a Bill to acquire land; plans had been prepared, and when alterations were made he believed the evils would be removed. The overcrowding at Dudley being reported, the Local Government Board urged the guardians to take steps to remedy the evil. Plans were submitted, but were held to be inadequate. Amended plans were prepared, and were now under consideration. As to the workhouses generally, he did not think the wards were overcrowded, nor had any complaint been made of the treatment of lunatic inmates.

Colonel Colthurst asked whether it was the intention of her Majesty's Government to take action with respect to the better treatment and disposal of lunatics in Irish workhouses, in accordance with the recommendation of the Commission appointed in 1878.—Mr. Trevelyan said a report was made to the late Government in 1879, recommending that the whole of the pauper lunatics should be placed under a separate department of the Local Government Board. The questions with which it dealt were so extensive that he could not pledge the Government to any definite course, but he would look into the matter further upon his return to Ireland.

**SALFORD ROYAL HOSPITAL.**—The fifty-fifth annual meeting of the subscribers to the Salford and Pendleton Royal Hospital and Infirmary was held on Monday at the Town Hall, Salford. The Mayor of Salford (Mr. Alderman Husband) presided. The treasurer of the institution read the annual report, from which it appeared that the number of patients admitted during the year had been: out-patients, 4321; accident patients, 4525; home patients 2606; hospital patients, 452; total 11,904. A more favourable account was able to be given this year of the financial condition of the hospital than was possible at the last annual meeting. The improvement was due mainly to the receipt of two instalments of £10,000 each of a legacy of the late Mr. J. Pendlebury. It was resolved to call a special meeting of the governors to discuss the desirability of continuing or abolishing the system of recommendation;

## Obituary.

### GEORGE CRITCHETT, F.R.C.S.

THE death of this esteemed and skilful surgeon and oculist has made a gap in professional and social ranks which it will be difficult to fill. Mr. Critchett had been suffering for eight weeks from cystitis and enlarged prostate and granular kidney, and died on the morning of Nov. 1st, having received all the aid that medical and surgical art could afford at the hands of Mr. Henry Morris, Drs. Andrew Clark and Liveing, and also Sir Henry Thompson and Mr. Walter Coulson. His death was apparently somewhat sudden, for he had, until the commencement of this his last illness, shown no signs of failing health, but had been throughout the past season attending to his practice with unabated vigour and success, as well as attending the meetings of the Ophthalmological Society, and performing all his numerous social engagements with his accustomed hospitality and courtesy. He was born in 1817, was apprenticed to Mr. John Scott of the London Hospital, where he entered as a student. He became a member of the Royal College of Surgeons in 1839, and Fellow in 1844 by examination. Before he rose to fame as an oculist he did much good work in general surgery at the London Hospital, where he was appointed demonstrator of anatomy, and afterwards (July 14th, 1846) assistant-surgeon, which latter office he held until his promotion to the office of full surgeon, in August, 1861. For fifteen years he faithfully discharged the arduous but unattractive duties of an assistant-surgeon at the London Hospital (duties more irksome in those days than now), but during this time he showed himself a master-hand in surgery, and established one or two very valuable methods of treatment, especially in ulcers of the lower extremity. He held the office of surgeon barely two years (from August 13th, 1861, to June 3rd, 1863), and resigned the more remunerative post for which he had laboured so long, solely in obedience to a feeling that he could not in fairness hold it longer, as he was so rapidly becoming absorbed in the work of ophthalmology at Moorfields and in private practice. He had, however, shown great skill as a surgeon and operator in other branches besides the eye; and demonstrated the fact, that while possessing the neatness and delicacy of touch for special eye operations, he had also the boldness and capacity for operations of larger magnitude, and there are many now living who can remember with pleasure his lithotomies and excisions of large joints.

Throughout nearly his whole professional life he had been associated with the Moorfields Eye Hospital, and it was here that the work which was most congenial to his tastes was found. As an operator he was perhaps unsurpassed. His views upon treatment were clear and precise. He was kind, courteous, and considerate to a degree, and in the height of his prosperity had always great regard for his less fortunate brethren. He was generous to a fault, but much of his generosity was not generally known. Nothing could exceed his delight in dispensing hospitality. His capacity for so doing was greatly increased by his refined taste in the arts, and his love of manly sports.

He became a Member of Council of the Royal College of Surgeons in 1870, and was President of the Hunterian Society for two successive years. In 1876 he succeeded Mr. Hulke as ophthalmic surgeon and lecturer on ophthalmic surgery at the Middlesex Hospital. As a teacher Mr. Critchett's influence was for the most part personal, but it was nevertheless profound. Its operation may be still traced in those who were his juniors and successors at Moorfields in 1864. He published in THE LANCET a course of lectures on ophthalmic surgery—a most masterly exposition of all information on the subject at that date, and containing many valuable original ideas.

The influence he has exercised in modern ophthalmic surgery has been very great, especially in operative procedures, for in nearly all operations, by his peculiar skill and care, he wrought small changes which guided others to some of the more important modifications, but the method of dividing the recti muscles by means of hook and scissors subconjunctivally was peculiarly his own, as was also the method of enucleation now usually practised. He devised

the operations of iridodesis and abscission, and although these procedures had to be abandoned for reasons that could not have been anticipated, they manifested the resources of an ingenious mind.

### BHOLA NATH BOSE, M.D., M.R.C.S. LOND.

WE regret to announce the death of Dr. Bhola Nath Bose, the late Civil Surgeon of Faradpore. He was one of the first four Bengalese gentlemen who came to England for the purposes of study in the year 1843. He distinguished himself in his college, gaining gold medals in materia medica, botany, and comparative anatomy, and certificates of honour in medicine, surgery, and midwifery. He graduated as M.D. Lond. in 1847. A reference to the London University Calendar will show that he was the first Indian who obtained that degree. He returned to India in 1848, where he was appointed an uncovenanted civil medical officer. During the Indian Mutiny of 1857 he served as a military surgeon, and discharged his duties in that capacity in so satisfactory a manner that the Government, in recognition of his service in the battle of Chillianwallah, awarded him a medal. Subsequently he was stationed at Faradpore as a civil surgeon, a post he held till 1876, when he took furlough for two years, and visited England for the second time. During his stay here he published his two works—namely, (1) "A New System of Medicine; entitled Recognisant Medicine, or the State of the Sick;" (2) "Principles of Rational Therapeutics, commenced as an Inquiry into the Relative Value of Quinine and Arsenic in Ague." After the expiration of his furlough he was allowed to retire with a pension of 333 rupees a month. For the last two years he had been living a retired life at Narkeldaugha, a suburb of Calcutta, suffering from time to time from headache, vertigo, and dimness of vision. About the middle of September last, however, he was attacked with a carbuncle at the back of the neck, which proved fatal on October 1st, 1882, after causing him intense pain for a period of sixteen days. He leaves a widow, but no children. Dr. Bose was born at Barakpore, a village twelve miles from Calcutta. His family, though respectable, were of comparatively humble status. He made his way by untiring labour, zeal, and perseverance. At the commencement of his career (1843) much courage was needed to break through caste and other prejudices of his countrymen in order to cultivate the learning of the West. During his stay at Faradpore for about nineteen years he used to visit patients at their houses free of charge, and during the prevalence of cholera and other epidemics he would go from house to house in his neighbourhood inquiring if anyone was ill. His history affords an encouraging example to Hindoos with a taste for medical and scientific pursuits.

## Medical News.

**ROYAL COLLEGE OF PHYSICIANS OF LONDON.**—In the list published last week Dr. Abrath was described as M.C. Heidelberg, instead of M.D. Heidelberg.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—The following gentlemen passed the Primary Examination in Anatomy and Physiology at meetings of the Board of Examiners on Monday, Tuesday, and Wednesday last:—

John Sykes, Henry Worsley, Lawson Gifford, Stanley M. Roome, Charles H. G. Brown, and James E. A. Fergusson, Edinburgh; Thos. G. Alexander, Robert R. Hunter, Mark Sharman, and Henry H. Ballachee, Glasgow; Edward Armitage, Richard P. Halliday, and John O. Ward, Leeds; William Graham, Dublin; A. T. G. Watts, Cambridge; Frank Woods, St. Bartholomew's Hospital; G. E. Deamer, University College and Edinburgh; J. W. Crowther, Birmingham; A. O. A. Packman, Sheffield; R. F. Castle, Cambridge; R. R. Giddings and G. M. Reid, Edinburgh; B. R. Johnston, Dublin; O. R. A. Julian, J. R. Forrest, W. J. Worleworth, Charles Downing, G. S. Leggett, R. H. Barrett, and Fredk. Sloman, St. Bartholomew's Hospital; T. J. Davis, T. H. Sykes, and T. M. Anglor, Liverpool; J. C. Michell, S. F. Smith, and T. G. Langhorne, London Hospital; Robert Denman and R. G. Silverlock, Guy's Hospital; J. F. W. Howitt, Toronto and Middlesex Hospital; A. E. Woods, St. George's Hospital; U. N. Mukerji, Cambridge and Edinburgh; Frederick Brentwall, Manchester; L. W. Burton, St. Thomas's Hospital; H. J. Butler, Leeds; Arthur Pring, Cambridge and Charing-cross Hospital; W. A. Dun, Cincinnati; Thomas Leicester, Liverpool and St. Thomas's Hospital; Charles Strickland, St. Bartholomew's Hospital and Hanover; W. F. Pridham and J. E. R. Grant, St. Mary's Hospital; C. E. Brooke, Cambridge and St. Bartholomew's Hospital; J. R. A. Bennett, University College.

# UNIVERSITY OF EDINBURGH.—The following gentlemen have passed the First Professional Examination:—

Anderson, William.  
 Anderson, W. A.  
 Antrobus, Edmund.  
 Bardgett, John.  
 Barraclough, T. W.

 Orr, J. F.  
 Paterson, W. W.  
 Ralley, J.  
 Ramsay, R.  
 Rankin, W.  
 Richmond, A.  
 Robertson, W.  
 Routledge, R.  
 Rutherford, T.  
 Seright, W.  
 Smith, J. C. A.  
 Sprott, G.  
 Stones, R. W.  
 Wands, J.  
 Whish, C.

Forty-nine candidates were rejected.

## SECOND PROFESSIONAL EXAMINATION.

Beveridge, Jno.  
 Birrel, J. R.  
 Colvin, F. H.  
 Cross, David.  
 Callen, William.  
 Greener, M. H.  
 Hawthorne, C. O.  
 Hinshelwood, Jas., M.A.  
 Jack, Alexander.  
 Jones, Evan.  
 Kendall, F. E.  
 Keogh, Arthur G.  
 Logan, Hugh.  
 Miller, Robert A.  
 Montgomery, A. N.  
 Morris, Geo. A.  
 Murdoch, J. W. A.  
 Macartney, Duncan, M.A.  
 M'Cracken, Wm.  
 M'Creadie, Wm.  
 Macdougall, Alexander.

Macleod, R. L. R.  
 Macrae, Alex. M.  
 Parker, James.  
 Peacock, Alexander.  
 Ritchie, Jno.  
 Robertson, Alexander.  
 Rutherford, Hy., M.A.  
 Scanlan, Jas.  
 Scott, Robert.  
 Service, R. M.  
 Shaw, Jas.  
 Sinclair, Jno.  
 Somerville, Wm. F., M.A.  
 Smith, Jas. P.  
 Smith, W. M.  
 Smith, D. M.  
 Spence, W. W.  
 Taylor, Francis.  
 Temple, Charles D.  
 Wilson, George.  
 Wright, Jno.

Twenty-nine candidates were rejected.

## THIRD PROFESSIONAL EXAMINATION.

Arthur, D.  
 Beveridge, R. E.  
 Blante, B.  
 Brown, W.  
 Brown, W. M.  
 Cameron, J.  
 Campbell, J. J.  
 Crawford, J. C.  
 Dunlop, J. I.  
 Forsyth, W. A.  
 Gemmell, J. F.  
 Gibb, W. F.  
 Gourlay, R.  
 Gray, W. L.  
 Hamilton, W. T.  
 Headrick, J. M.  
 Herbertson, J., M.A.  
 Hodge, P.  
 Hogg, G. M.  
 Howie, A.  
 Johnston, A.  
 Johnston, F.

Kerr, Jno.  
 Marquis, D.  
 Martin, W.  
 Morrison, A.  
 Macarthur, B. N.  
 Macdonald, J.  
 Mackenzie, D.  
 Maclean, A.  
 MacNaught, J. B.  
 Prangwell, J. T.  
 Pretsell, W. G.  
 Quaike, W. F., B.A.  
 Richard, D. T.  
 Russel, J.  
 Soga, W. A.  
 Stafford, W.  
 Steele, R. G.  
 Taylor, W. C.  
 Turnbull, E. T.  
 Vost, W.  
 Williams, A.

Seventeen candidates were rejected.

# ROYAL UNIVERSITY OF IRELAND.—The following Degrees were conferred on the 8th inst. by his Grace the Duke of Abercorn, Chancellor of the University:—

## M.D. DEGREE.

FIRST CLASS HONOURS.—Charles H. Wise.

## SECOND CLASS HONOURS.

M'Murray, J. | Adams, F. E.

## UPPER PASS DIVISION.

Allport, C. W.  
 Austin, J. J.  
 Barnes, W. S.  
 Bell, T. G.  
 Cromie, Thomas.  
 Heanen, Charles.  
 Jackson, Mark.

Kelly, Michael.  
 Lindsay, J. A.  
 O'Keeffe, W.  
 Prendergast, J. M.  
 Swan, S. A. L.  
 White, Daniel.

## LOWER PASS DIVISION.

Brown, H. E.  
 Chambers, A. B.  
 Cooke, James.  
 Gibson, William.  
 Good, William.  
 Graham, J. S.  
 Graham, William.  
 Hamilton, William R.  
 Hawthorne, A. W.  
 Henderson, S. D.  
 Henry, James.

Hunter, J. F.  
 Legge, R. J.  
 M'Cambridge, J.  
 M'Dermott, Cornelius.  
 M'Manus, L. S.  
 Mathews, R. H.  
 Moran, John P.  
 Moynan, R. M.  
 Orr, J. Morrison.  
 Smith, R. Strafford.  
 Wilson, James.

## M.B. DEGREE.

UPPER PASS DIVISION.—John Riordan.

## M.CH. DEGREE.

Atock, M. H.  
 Austin, J. J.  
 Barnes, W. S.  
 Bell, T. G.  
 Black, J. G.  
 Chambers, A. B.  
 Craig, James.  
 Cromie, Thomas.  
 Gallwey, P. J.  
 Gibson, W. Walter.  
 Haines, H. A.  
 Hamill, Samuel.  
 Hamilton, William R.  
 Hawthorne, A. W.  
 Heanen, Charles.  
 Henderson, S. D.  
 Henry, James.  
 Lindsay, J. Alexander.  
 Lithgow, J. M'G.

M'Cambridge, J.  
 M'Connell, T. S.  
 M'Dermott, C.  
 M'Donnell, J. R.  
 M'Manus, L. S.  
 M'Murray, J.  
 Mathews, R. H.  
 Moran, John P.  
 Morell, L. D.  
 Moynan, R. M.  
 O'Connell, D. V.  
 O'Keeffe, Matthias.  
 O'Keeffe, William.  
 Prendergast, J. M.  
 Riordan, John.  
 Rountree, G. A.  
 White, Daniel.  
 Wilson, James.  
 Young, J. V.

## DIPLOMA IN OBSTETRICS.

Adams, F. E.  
Allport, C. W.  
Chambers, A. B.  
Cromie, Thomas.  
Gibson, William.  
Haines, H. A.  
Lyons, R. W. S.

M'Murray, J.  
Maguire, C. J. O'Leary.  
Mathews, R. H.  
O'Keefe, William.  
Prendergast, J. Moran.  
Rountree, G. A.

**APOTHECARIES' HALL.**—The following gentlemen passed the examination in the Science and Practice of Medicine, and received certificates to practise, on Nov. 2nd:—

Smith, Ebenezer Thos. Ayden, Abbey-street, Bermondsey.  
Spencer, Walter, Doughty-street.  
Statham, Reginald Whitehead, St. Peter's Rectory, Walworth.

The following gentlemen also on the same day passed the Primary Professional Examination:—

Harold Wm. Banfield and Raheem Buksh, London Hospital; Arthur Dixon Jollys, Charing-cross Hospital; George Wm. Burgess Slader, Guy's Hospital.

**UNIVERSITY OF CAMBRIDGE.**—The number of students commencing dissection (i.e., second-year students) this session is 65.

**QUEEN'S COLLEGE, BIRMINGHAM.**—At this college there are 36 new entries, two dental students, and one for special classes.

**ST. MARY'S HOSPITAL, MANCHESTER.**—Messrs. G. and R. Dewhurst have given £100 towards the extinction of the debt on this charity.

**SOCIETY FOR THE ENCOURAGEMENT OF ARTS, MANUFACTURES, AND COMMERCE.**—The first meeting of the 129th session of this Society will be held on Wednesday, the 15th inst., when the opening address will be delivered by Dr. Siemens, Chairman of the Council.

**THE ROYAL NATIONAL HOSPITAL FOR CONSUMPTION, VENTNOR.**—H.R.H. the Duke of Albany has intimated to the Board of Management his willingness to preside at a public dinner next spring in aid of the funds of the Ventnor Consumption Hospital.

**POLICE AMBULANCE CLASSES.**—On the 3rd inst., at Scotland-yard, Major-General Burnaby presented certificates to the members of the police force who had passed the examination of the St. John Ambulance Association. The number of men examined was 102, of whom 90 were successful.

**SUPERANNUATION ALLOWANCES.**—Mr. J. Hatton, L.R.C.P. Ed., M.R.C.S., district medical officer, Monmouth Union, has been awarded a superannuation allowance of £26 a year.—Mr. W. Barr Brown, M.R.C.S., L.S.A., late district medical officer of the Windsor Union, has been awarded an allowance of £30 a year.—Dr. Coulter, of the South Dublin Union, has been granted a retiring allowance of £130 per annum.

AN adjourned meeting of the Governors of the Yorkshire Hospital for Incurable Diseases, held at Leeds last week, seems to have been one at which the proceedings might very properly be called lively. Doubts appear to have been expressed of the soundness of the condition of the institution financially, but a committee having been appointed to investigate the matter, and their report having been regarded as satisfactory, the meeting terminated with mutual congratulations.

**MEDICAL SOCIETY, COLLEGE OF PHYSICIANS IN IRELAND.**—The following office-bearers have been appointed for the ensuing year:—President: William Moore. Vice-Presidents: F. R. Cruise and Henry Kennedy. Council: J. Hawtrey Benson, Fleetwood Churchill, J. Magee Finny, A. Foot, Samuel Gordon, T. W. Grimshaw, A. Jackson, J. W. Moore, Christopher Nixon, J. H. Purker, and W. G. Smith. Hon. Secretary and Treasurer: Alexander Nixon Montgomery.

**HYDROPHOBIA.**—Another instance of the length of time hydrophobic virus may be retained in the system before developing itself has been furnished during the past week by the death of a child in Guy's Hospital from this disease. At the inquest held on Monday it was stated that the deceased, a girl aged fourteen, had been bitten on the hand by a dog two years ago. The wounds eventually healed up and nothing more was thought of the matter until three weeks ago, when the girl complained of feeling unwell and remained in bed. When water was brought near her she was seized with a paroxysm of fear, and when

milk was offered to her she raved and cried piteously. She was conveyed to the hospital convulsed and foaming at the mouth, and expired almost immediately after admission. This case is worthy of note on account of the long period that elapsed between the receipt of the bite and the fatal result. In a case which happened a few years ago, a passenger to Australia by a sailing vessel, on which no dog was carried, at the conclusion of the voyage, which had occupied four months, was seized with hydrophobia. In the intervals of his paroxysms he was able to inform those near him that he had been bitten by a dog eighteen months previous to his departure from England, so that the virus had lain dormant in this case also for nearly two years.

**SANITARY INSTITUTE OF GREAT BRITAIN.**—At an examination for Local Surveyors and Inspectors of Nuisances held on November 2nd and 3rd, eight candidates presented themselves. The Institute's certificate of competency to discharge the duties of Local Surveyor was awarded to C. H. Cooper; and the Institute's certificate of competency to discharge the duties of Inspectors of Nuisances was awarded to J. Brown, S. C. Legg, D. Richards, A. Taylor, and J. Watson.

**VACCINATION GRANTS.**—The following gentlemen have received the Government grant for efficient vaccination in their respective districts:—Dr. William Hoffmeister of Cowes, Isle of Wight (fourth time); Mr. W. Birtwhistle, Swadford, Skipton (second time); Mr. J. H. Hughes, Ombersley district, Droitwich (fourth time); Mr. T. H. Tidswell of Morecambe (second time); Mr. S. Wellesley Coombs, Claines district; Mr. H. O. Westwood of Prees, Shropshire; Mr. John Wionall George of Leigh.

**MONUMENT TO THE LATE SURGEON-MAJOR SIMPSON.** A handsome and very chaste tablet in white marble, and after the form of a partly unfolded scroll, has recently been erected in the vestibule of the Free Church, Kintore, bearing the following inscription:—"Surgeon-Major John Simpson, H.M. 23rd Regiment, Bombay N.L.I. Died at Sibi, Southern Afghanistan. In affectionate remembrance this tablet is erected by his brother officers." Surgeon-Major Simpson was the fourth son of the late Dr. Robert Simpson, first minister of the Free Church at Kintore.

**ORDER OF ST. JOHN OF JERUSALEM.**—The committee of the Jerusalem Hospice Fund has made arrangements for opening immediately a temporary dispensary at Jerusalem pending the erection of the building a site for which has been granted by the Sultan to the Order of St. John. Dr. J. C. Waddell, who has had special experience in ophthalmia, has left England for Jerusalem to commence work. Letters have lately, we learn, been received from Mrs. Burton the well-known authoress, Sir Austin Layard, and others, testifying to the fearful sufferings caused by this disease. Subscriptions will be received from those interested in this matter by Lady Lechmere, 13, Bolton-row, W., and Captain Dallas, Treasurer, St. John's Gate, Clerkenwell, E.C.

## Medical Appointments.

Intimations for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning at the latest.

ANGEL, MR. ARTHUR, has been reappointed Public Analyst or Southampton.  
CHISHOLM, J. M., M.A., M.D., C.M., M.R.C.S., has been appointed Visiting Physician to the Liverpool Convalescent Hospital, Woolton.  
EVANS, THOMAS, M.D. Ed., L.R.C.S., has been reappointed Medical Officer of Health for the Llandisilio District of the Aberystwyth Union.  
FIRTH, EUSTACE, M.B., C.M. Edin., has been appointed Medical Officer to the Norwich Dispensary, vice Charles Firth, resigned.  
FRANKISH, WILLIAM JOHN, L.R.C.P. Lond., M.R.C.S., has been elected Surgeon to the Chelsea, Brompton, and Belgrave Dispensary.  
HEHNER, MR. OTTO, has been reappointed Public Analyst for Southampton.  
JACKSON, JOHN HENRY, M.B., C.M. Ed., has been elected Junior House-Surgeon to the Wigan Infirmary, vice A. W. Stone, L.R.C.P. Ed., M.R.C.S., resigned.  
KEMPE, J. ARTHUR, M.R.C.S., L.R.C.P. Lond., has been appointed a Senior Demonstrator of Anatomy at University College.  
KIDD, PERCY, M.B., M.R.C.P. Lond., has been appointed Pathologist and Curator to the Hospital for Consumption and Diseases of the Chest, Brompton.  
MACLEAN, KENNETH, L.R.C.P., L.R.C.S., has been appointed Honorary Surgeon to the Stockport Infirmary, vice J. D. Bow, M.B., deceased.

**ORE, J. B. G. GIDLEY, M.R.C.S.,** has been appointed Medical Officer for the First District of the Ongar Union.

**RRAY, ANDREW, M.B.Dub.,** has been appointed Medical Officer to Hampstead Provident Dispensary, vice W. H. Cook, M.D., deceased.

**TER, Dr. JOHN,** has been reappointed Public Analyst for Bermondsey.

**INTON, J. CRAWFORD, M.D.Ed.,** has been appointed Surgeon to the Dispensary of the Western Infirmary, Glasgow.

**OWART, WILLIAM RIBTON, L.R.C.C.P.I., L.R.C.S.I.,** has been appointed Medical Officer for the Eighth District of the Norwich Union.

**ALKER, WILLIAM H. S., L.R.C.C.P.I., L.R.C.S.I., &c.,** has been appointed Resident Medical Officer to the Hospital for Sick Children, Glasgow.

**HITFORD, WILLIAM, M.D., M.Ch.Q.U.I.,** has been appointed Honorary Medical Officer to the North Dispensary, Liverpool.

**HITTLE, GLYNN, M.A., M.D.Cantab., M.R.C.P.L., M.R.C.S.,** has been appointed Honorary Medical Officer to the North Dispensary, Liverpool.

## Births, Marriages, and Deaths.

### BIRTHS.

**DUKE**.—On the 2nd inst., at the residence of her mother, Berners-street, Ipswich, the wife of Surgeon-Major Duke, of a son.

**LITTLE**.—On the 9th inst., at Dalkeith Lodge, Merton-road, Wimbledon, the wife of Dr. Edward Little, of a son.

**MACKENZIE**.—On the 1st inst., at Finsbury-square, the wife of Stephen Mackenzie, M.D., F.R.C.P., of a daughter.

**ORME**.—On the 4th inst., at Great Berkhamsted, the wife of Robert Orme, M.R.C.S.Eng., of a daughter.

**POIGNAND**.—On the 2nd inst., at Upper-street, N., the wife of Malcolm Poignand, M.D., of a son.

**SMITH**.—On the 1st inst., at Belmont House, Newport, Essex, the wife of William Alexander Smith, M.A., M.B.Oxon., of a daughter.

**TICEHURST**.—On the 27th ult., at Stichester House, St. Leonards-on-Sea, the wife of A. R. Ticehurst, M.R.C.S. &c., of a daughter.

**TURNER**.—On the 1st inst., at Camden-road, the wife of T. Bryett Turner, M.R.C.S., of a daughter.

**WALLACE**.—On the 3rd inst., at Cleeckheaton, Yorkshire, Constance, the wife of Edward J. Wallace, M.D., of a son.

**WHEELER**.—On the 4th inst., at Pembroke-gardens, W., the wife of John Wheeler, M.D. & C.M., of a daughter.

**WHITTINGTON-LOWE**.—On the 2nd inst., at Eaton-place, Brighton, the wife of R. Whittington-Lowe, M.D., Staff-Surgeon, of a son.

**WILLIAMS**.—On the 3rd inst., at Sherborne, Dorset, the wife of W. H. Williams, M.R.C.S., L.R.C.P.Lond., of a daughter.

### MARRIAGES.

**BOLSTER—CARPENTER**.—On the 1st inst., at St. James's Church, Exeter, by the Rev. Canon Bolster, M.A. (brother of the bridegroom), assisted by the Rev. George E. Carwithen, M.A., R.N., Staff-Surgeon Thomas Bolster, R.N., of the Royal Naval Hospital, Plymouth, eldest son of the late Richard Bolster, Esq., of Nummerville, co. Cork, to C. H. Laura C., third daughter of the late Rev. Charles Carpenter, Vicar of Week, St. Germans, North Devon.

**BRIGHAM—CARTWRIGHT**.—On the 7th inst., at St. Peter's and St. Paul's, Kilton, near Boston, by the Rev. E. Marshall, Curate-in-charge, assisted by the Rev. A. C. Rowley, Vicar of Satterton, John King Brigham, M.A., M.D., elder son of the late James Brigham, of Donegal, Ireland, to Mary (Pollie), youngest daughter of the late John Cartwright, of the Manor House, Timberland, Sleaford, Lincolnshire.

**LATHAM—ROBINSON**.—On the 7th inst., at Presdon, George Latham, L.R.C.P., of Highfields, West Bromwich, to Jane, youngest daughter of the late James Robinson, of Moor-park, Preston, Lancashire.

**MCCNEILL—PITT**.—On the 2nd inst., at Cullompton; Devon, John P. McNeill, B.A., M.D.T.C.D., of Knockmore, near Ballymoney, co. Antrim, and Fiverton, Devon, to Louisa, youngest daughter of the late William Pitt, Esq., of Southwell Lodge, Trull, near Taunton, and Woodcock's Well, near Cullompton.

**REYNOLDS—BOWERS**.—On the 28th ult., at Holy Trinity Church, Southampton, Robert Reynolds, second son of the late Dr. William Reynolds, of Wellington, Somerset, to Isabella Maria, third daughter of J. Bowers, Esq., of Southampton.

**TOOTH—PRICE**.—On the 31st ult., at St. John's Church, Weston-super-Mare, Howard Henry Tooth, M.B., of Harley-street, eldest son of the late Frederick Tooth, of Brighton, to Mary Beatrice, youngest daughter of the late Edward Price, of Highgate.

**WEBB—HUNTING**.—On the 2nd inst., at Jesmond Church, Newcastle-upon-Tyne, Henry Pelham Webb, M.B., of Wymering-terrace, Lavender-hill, S.W., to Fannie, daughter of Charles Hunting, of South Heston, co. Durham.

### DEATHS.

**ALLEYNE**.—On the 9th September, at Sydney, New South Wales, Haynes Gibbs Alleyne, M.D.Edin., President of the Medical Board, aged 69.

**DEELEY**.—In loving memory of Cissy, the dear wife of Ambrose W. Deeley, who died on Sunday, Nov. 5th, 1882, aged 29 years.

**LOWELL**.—On the 12th ult., at Brooklyn, New York, Abram Leland Lowell, M.D., aged 50.

**SOULBY**.—On the 4th inst., very suddenly, from disease of the heart, at Waverley House, Hull, Henry Soulby, M.D.St. And.

## METEOROLOGICAL READINGS.

(Taken daily at 5.30 a.m. by Steward's Instruments.)

THE LANCET OFFICE, Nov. 9th, 1882.

Data.	Barometer reduced to Sea Level and 32° F.	Direction of Wind.	Dry Bulb.	Wet Bulb.	Solar Radiation in Vacuum.	Max. Temp. Shade.	Min. Temp.	Rain fall.	Remarks at 8.30 a.m.

## Medical Diary for the ensuing Week.

### Monday, Nov. 13.

**ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS**.—Operations, 10½ A.M. each day, and at the same hour.

**ROYAL WESTMINSTER OPHTHALMIC HOSPITAL**.—Operations, 1½ P.M. each day, and at the same hour.

**METROPOLITAN FREE HOSPITAL**.—Operations, 2 P.M.

**ROYAL ORTHOPEDIC HOSPITAL**.—Operations, 2 P.M.

**ST. MARK'S HOSPITAL**.—Operations, 2 P.M.; on Tuesday, 9 A.M.

**MEDICAL SOCIETY OF LONDON**.—Dr. Richardson, "On Ammoniated Chloroform as a Preservative of Animal Tissues."—Mr. T. Knowsley Thornton, "On Three Cases of Successful Nephrectomy, with Remarks on Operation."

### Tuesday, Nov. 14.

**GUY'S HOSPITAL**.—Operations, 1½ P.M., and on Friday at the same hour.

**WESTMINSTER HOSPITAL**.—Operations, 2 P.M.

**WEST LONDON HOSPITAL**.—Operations, 3 P.M.

**ROYAL MEDICAL AND CHIRURGICAL SOCIETY**.—8.30 P.M. Dr. Vary Lyle, of Durban, "On the Endemic Hematuria of the S.E. Coast of Africa." The paper will be illustrated by specimens of the Bilharzia Hematobia, exhibited by Dr. Cobbold and Dr. Radcliffe Crocker.—Mr. A. P. Thomas, of Oxford, will exhibit Drawings and Microscopic Preparations, and make some remarks on his "discovery of the life history of the liver fluke, and its introduction into the bodies of sheep."—Dr. Cobbold will also exhibit Specimens of the various forms of Fluke from Man, the Elephant, and the Giraffe.—Flat and Nematoid Worms will be exhibited by Dr. Bastian, and illustrated with models and drawings by Professor Ray Lankester.—Dr. Stephen Mackenzie will show the Filaria Sanguinis Hominis from Human Blood, and also from the Stomach of the Mosquito.

### Wednesday, Nov. 15.

**NATIONAL ORTHOPEDIC HOSPITAL**.—Operations, 10 A.M.

**MIDDLESEX HOSPITAL**.—Operations, 1 P.M.

**ST. BARTHOLOMEW'S HOSPITAL**.—Operations, 1½ P.M., and on Saturday at the same hour.

**ST. THOMAS'S HOSPITAL**.—Operations, 1½ P.M., and on Saturday at the same hour.

**ST. MARY'S HOSPITAL**.—Operations, 1½ P.M.

**LONDON HOSPITAL**.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

**GREAT NORTHERN HOSPITAL**.—Operations, 2 P.M.

**SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN**.—Operations, 2½ P.M.

**UNIVERSITY COLLEGE HOSPITAL**.—Operations, 3 P.M., and on Saturday at the same hour.—Skin Department: 1.45 P.M., and on Saturday at 9.15 A.M.

### Thursday, Nov. 16.

**ST. GEORGE'S HOSPITAL**.—Operations, 1 P.M.

**ST. BARTHOLOMEW'S HOSPITAL**.—1½ P.M. Surgical Consultations.

**CHARING-CROSS HOSPITAL**.—Operations, 2 P.M.

**CENTRAL LONDON OPHTHALMIC HOSPITAL**.—Operations, 2 P.M., and on Friday at the same hour.

**HOSPITAL FOR WOMEN, SOHO-SQUARE**.—Operations, 2 P.M.

**NORTH-WEST LONDON HOSPITAL**.—Operations, 2½ P.M.

**HARVEIAN SOCIETY**.—The Report of the Alcohol Committee.—Dr. Francis, "On the Treatment of Neuralgia."

### Friday, Nov. 17.

**ST. GEORGE'S HOSPITAL**.—Ophthalmic Operations, 1½ P.M.

**ST. THOMAS'S HOSPITAL**.—Ophthalmic Operations, 2 P.M.

**ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL**.—Operations, 2 P.M.

**KING'S COLLEGE HOSPITAL**.—Operations, 2 P.M.

**SOCIETY OF MEDICAL OFFICERS OF HEALTH**.—7½ P.M. Mr. Rogers Field, "On some of the less recognised but important points in the Drainage and Ventilation of Houses."

### Saturday, Nov. 18.

**KING'S COLLEGE HOSPITAL**.—Operations, 1 P.M.

**ROYAL FREE HOSPITAL**.—Operations, 2 P.M.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

## Notes, Short Comments, and Answers to Correspondents.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*All communications relating to the editorial business of the journal must be addressed "To the Editor."*

*Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.*

*Lectures, original articles, and reports should be written on one side only of the paper.*

*We cannot prescribe, or recommend practitioners.*

*Local papers containing reports or news-paragraphs should be marked.*

*Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."*

### MEDICAL KNOWLEDGE AND THE MUNICIPAL CONSTITUENCIES.

MR. GENTLES, at the recent municipal elections in Derby, found some disadvantage in holding intelligent opinions on matters of public health, such as that small-pox is a deadly, loathsome, hideous disease, to be regarded as a national calamity, and to be guarded against, and that, even at the cost of a little addition to the rates, and possibly a little curtailment of private liberty, public health must be secured. He made an able and unanswerable defence of the vaccination laws, and even his opponents allow that he made a great impression on the less fanatical members of the anti-vaccination party. It is better to lose an election, as Mr. Gentles did—though not by a large majority—than to gain it by pandering to ignorance and fanaticism. Education is abroad, and men who are faithful to science and to common sense will not always be rejected.

Dr. Ed. Thompson (Omagh).—We shall be glad to receive communications of an interesting nature as occasion may offer.

### "THE USE OF THE FORCEPS IN MIDWIFERY."

*To the Editor of THE LANCET.*

SIR,—The object of my writing to you on the above subject was not, as your correspondent, Mr. Isaac Williams, seems to infer, to deprecate the more frequent use of the forceps. On the contrary, it was in consequence of an assertion made by a correspondent in a previous number of THE LANCET, that the forceps were not required in more than one in 600 or 700 cases, that I was led to lay before the profession the experience of their use in 400 consecutive cases, of which notes had been kept by one who objects to a too meddlesome practice.

I purposely did not give my reasons for their employment, because those reasons were such as may be found in any modern text-book on midwifery, and likewise because I desired to keep my letter within the reasonable limits demanded by the crowded columns of your valuable journal. For the latter reason I do not propose to reply to Mr. Williams's criticisms *seriatim*. I am very strongly inclined to think, however, that when he has acquired a little more practical experience than he has probably had during the brief period he has been a qualified practitioner, he will find that, as a rule, three hours will be the longest time he can wait (with advantage to his patients) before applying the forceps, or adopting some alternative, when there is no advance in the second stage of labour. My remark concerning the proportion in which the forceps were said to have been used by the late master of the Rotunda had no reference to their particular necessity or otherwise at that institution, but rather to what seemed to me to be an unnecessary and undesirable frequency in their use in private practice. In this opinion I venture to say that I should be borne out by the great bulk of the profession. *In medias res tutissima* is, as a rule, a tolerably safe motto in midwifery as in other affairs of life. The proportion of cases in which the forceps used to be employed, as stated by Dr. Churchill, was about one in 115, but I suspect that if the collective experience of the younger generation of practitioners were gathered together the proportion in which they would be found necessary or desirable would be much nearer one in thirty or forty. The whole subject was, however, so fully discussed at the Obstetrical Society, and reported in your columns some two or three years since, that it would be presumption on my part to say anything further.

Nov. 6th, 1882.

"TRICYCLES."

*To the Editor of THE LANCET.*

SIR,—Permit me to note, in correction of the view of your correspondent of last week, a possible danger to women in tricycle-riding. Quite lately a patient of mine aborted after a long tricycle-ride. She herself mentioned this as a probable cause.

Islington, Oct. 30th, 1882.

I am, Sir, yours respectfully,

J. CHALMERS.

### SICK ALLOWANCES WORKMEN.

In reference to the measures which the German Parliament has been considering relative to the provision for workmen suffering from illness, it has been feared in some quarters that the scheme, if carried into effect, would encourage workmen to simulate indisposition with a view of profiting by the enactment. A petition has been sent from the Saxony coal district, which states that one of the local benefit societies used, up to the year 1879, to give a sick allowance varying from 55 per cent. of the normal wages in cases of slight indisposition to 72½ per cent. when the illness was of a severe character. When, in 1880, this scale of allowance was reduced by about one quarter, there was a decrease of about 45 per cent. in the amount which the society was called on to pay, while the general sanitary condition of the neighbourhood had not improved. The number of claims showed even a greater reduction. The petition likewise urges that the option which workmen would have of contributing at the same time to several provident organisations should be withdrawn, and that in any legislation on this subject care should be taken that the position of a workman who claims upon a sick fund should not be of such a nature as to render it more profitable for him under some circumstances to be at home than to be following his occupation.

Mr. A. Davidson.—The question was decided at the Southwark Police-court on Feb. 18th, 1882, in a case in which the magistrate dismissed a summons with costs against the School Board (see THE LANCET of Feb. 23rd, page 329).

Mr. F. T. Batchelor.—The Royal Medical Benevolent College, Epsom. Office, 37, Soho-square, whence a prospectus may be obtained.

Mr. Parnell.—We have frequently commented on the risk of the spread of contagious diseases by means of letters and books.

Mr. W. W. Morgan.—We fear we should not have space for the publication of an article of the nature described.

M.D. has not enclosed his card.

### ENGLISH SPORTS.

*To the Editor of THE LANCET.*

SIR,—The following report is extracted from the *Daily Telegraph* of Wednesday, Nov. 1st :—

"Catching the Stag.—Our Oswestry correspondent telegraphs: 'The annual sport of catching the stag to be hunted on the anniversary of the Earl of Powis's birthday took place yesterday morning in Powis Castle-park, Welshpool. His lordship and a number of equestrians—ladies and gentlemen—were present, and a large field of pedestrians. The stag was pursued by men on horseback and on foot, but not by hounds. After an hour's pursuit the stag fell dead. His lordship gave another stag, which ran for about an hour up and down the park, and was ultimately taken in the net. The stag seemed somewhat distressed, and after his horns were cut off the fine animal died. This second fatality created a great sensation, and the hunt was at once abandoned.'"

Assuming the above to be true, it would be interesting to know whether his lordship and friends belong to the anti-vivisection party. I am surprised that such gross brutality is allowed in a country where vivisection, for possible and probable good to human kind, is guarded by most stringent laws, and which possesses a Society for the Prevention of Cruelty to Animals. Without further comment on the apparent inconsistency of the law on the subject,

I am, Sir, yours obediently,

Battersea-park, S.W., Nov. 3rd, 1882.

A. PHILLIPS HILLS.

Dr. R. de Musgrave Clay.—The pamphlet is a reprint from the Transactions of the Colorado State Medical Society, 1882, and is printed by Edwin Price and Co., Denver, Colorado.

Mr. Phillips Hill, Mr. Chittenden, Dr. Lownds, and others.—No doubt the proceeding is objectionable.

M.R.C.S.—We are not aware.

### "REMOVAL OF HAIR FROM THE FACE."

*To the Editor of THE LANCET.*

SIR,—Your correspondent, "A Puzzled Practitioner," asks in your last issue "by what means he can permanently remove a patch of hair from a prominent position of a patient's face?" May I suggest the following treatment, which I have seen very successful in several instances. It is applicable both for the removal of hair and moles.

A small cantery is necessary. It should be something of the following form :—From a small bone handle passes a stem of platinum-wire three inches long, curved at a right angle half an inch from the end, which resembles a blunt needle. At the angle is a bead-like bulb, which serves as a reservoir for the heat when in use. The bulb and point having been made white hot in the flame of a spirit-lamp, the affected skin (previously shaved) is to be deeply punctured by a number of stabs, close together, and over a space of about a sixpence. Repeated heatings of the cantery will be required, but the process is almost painless, and when the sore heals a white cicatrix will appear, free from pigmentation or hair bulbs. The same process can be repeated at subsequent sittings until the whole affected area is cured. I do not remember the name of the cantery or the maker, but I could easily procure these particulars should your correspondent desire it.

Plymouth, Nov. 5th, 1882.

I am, Sir, yours, &c.,

G. C.

## THE ASSISTANTS' EXAMINATION AT THE APOTHECARIES' HALL.

A CORRESPONDENT directs our attention to this examination and to the useful and deserving character of the men who pass it, and their fitness for the dispensing work of medical men, hospitals, and dispensaries. We see no objection to the use of the letters he specifies, if they are not used unnecessarily, or in a way to convey the impression that they imply medical qualification.

## "INUNCTION IN SCARLATINA."

To the Editor of THE LANCET.

SIR,—Your correspondent, "Cutis," having apparently had his faith shaken as to his hitherto satisfactory treatment of scarlet fever by the inunction of camphorated oil, has appealed to your readers for their opinions or experience of the matter. While I cannot lay claim to any personal practical knowledge of this particular mode of treating our worst eruptive pestilence, still, after a fairly extensive observation of the too-familiar disease, and reasoning *a priori* from well-established and acknowledged facts, I must say I should be inclined, if you will allow me, to add my veto to that of his experienced friend.

There cannot be a doubt that two most important objects in our treatment of the fever are diminution of temperature and elimination of the fever poison, be it what it may—presumably bacterial. Now, it is difficult to conceive how inunction into the general integument can possibly accomplish these; and in truth it is not easy to understand what therapeutic process can possibly be initiated, or what benefit can be secured by its employment. The oil must have the effect of clogging up, more or less completely, the openings of the multitudinous ducts of the sweat-glands, through which, as one of the emancipatory channels, nature is endeavouring to remove the ever-growing poison, as well as the results of the general tissue-change, now abundantly present, due to the elevated temperature. And there is the more danger in thus checking this eliminative function just when the vital processes are weak and the skin congested and its function to some extent paralysed by the pyrexia which the non-elimination would only tend to sustain or even raise. Elimination from the general surface ought rather to be encouraged and helped instead of checked and weakened; the extensive cutaneous area, with its enormous supply of secreting structure, ought to be sedulously utilised. For certainly, owing to the close structural and functional intimacy and similarity of the skin and the internal organs—more especially the kidneys—a vast amount of additional labour must vicariously be imposed on the renal function of tissue and poison removal if the work of the great skin-gland be in abeyance. There is every reason to suppose that the scarlatinal poison produces congestion of the tubules of the kidney as well as of the skin and mucous membranes, and they are now further overburdened with the task of removing the excessive nitrogenous waste of the febrile state; so that any check to cutaneous transpiration which the dense oil molecules must effect cannot, I think, but be injurious not only to the kidneys, but to the fever-stricken system generally. The tissues thus become doubly poisoned: heat-loss and waste-removal are more or less interfered with, as well as the escape of the virus.

I am aware the late Dr. W. Budd advocated the use of antiseptic inunction in the desquamative stage for the hygienic purpose of preventing the spread of the infective material, and this may be less objectionable now that the pyrexia is gone and tissue-change less active; but even here, from some cases in my recollection, I cannot but think that while it may be a decided good for others, it is of very doubtful advantage to the patient.

Judging, then, from these considerations, I should say that inunction may be a perilous proceeding, because, by diminishing cutaneous elimination, it may increase the blood-poisoning, and cripple ultimately the renal excretory work, and is thus calculated to induce albuminuria and acute rheumatism—evils which are quite apt enough to follow under even the most favourable conditions. If "Cutis" has hitherto entirely escaped these results in the course of his inunction treatment, I cannot but regard him and his patients as fortunate, and heartily congratulate him. Either his cases must have been of a mild type, or our physiology and pathology are visionary and hypothetical.

Much the most satisfactory treatment—if any treatment of this eruptive fever can yet be considered satisfactory—I have found to be the wet pack-sheet or cold bath at the very onset of rising temperature, combined with the internal administration of salicin and carbonate of soda, and local antiseptic applications to the fauces as required. Surface elimination is thereby encouraged, while the temperature is usually materially lowered.—I am, Sir, yours faithfully,

D. BEATTIE BAIN, M.B., C.M. Ed.

Tay-street, Dundee, Oct. 31st, 1882.

## "FORTUNATELY HIS MERITS DESCEND TO HIS SON AND SUCCESSOR."

To the Editor of THE LANCET.

SIR,—The above heading is an extract from a paragraph in a recent daily paper referring to the lamented death of an eminent surgeon.

It is to be regretted that statements of this kind should get into the lay press; they savour too much of "the business carried on as usual" character to be agreeable to the medical reader, and a gentleman thus eulogised must always regret the false position he is placed in by his injudicious admirer.—I am, Sir, yours obediently,

Dalby-square, Cliftonville, Margate

WM. KNIGHT TREVES.

Nov. 2

## "EDUCATION BASED ON THE LAWS OF HEREDITY."

To the Editor of THE LANCET.

SIR,—The article that appeared in your columns of October 28th on the above subject opens a field for discussion of an interesting and important nature, for though the subject is familiar to the psychological physician, it has not received much attention from the rank and file of the profession, who have such excellent opportunities for instructing and counselling parents and teachers. There can be no doubt that not only should the education of the individual child be conducted with an intelligent recognition of its hereditary tendencies both mental and physical, but a careful observation should be kept of his innate proclivities and tastes, and if these coincide, as is very frequently the case, with a certain shape, development, and size of cranium, an opinion may be formed, not necessarily an infallible one, but of sufficient general correctness to be well worth consideration, in deciding the details and lines of education, and to influence the selection of his vocation in life. By such a system how many failures in life such as we frequently witness might be avoided? How many clergymen, for instance, whose lives are a perpetual repression of their natural tastes and inclinations, might have succeeded well, and even distinguished themselves, as colonists, farmers, engineers, soldiers, or lawyers? They would have been far happier individually, and would not have occupied a position they could not adorn to the exclusion of a man whose hereditary mental and moral characteristics were of a congenial kind, and to whom in consequence the study, the restriction, and the duties of clerical life were not irksome, but pleasurable. I am not writing as an advocate for the revival of the pseudo science of phrenology, but I think few will dispute that the size and shape of the head is a guide to the measure of intellectual capacity, and the possession of certain proclivities and tastes; and if we can direct the selection of a vocation in accordance with these innate proclivities and preferences—or, at all events, not in direct opposition to them—we shall be rendering a service to both the individual and the community. At present I am convinced the great majority of middle-class parents bestow very little thought on the probable fitness or unfitness of a boy for a given vocation. If an opportunity offers for what is termed "a start in life," it is often seized without any consideration as to whether the hereditary characteristics of the recipient are such as will render the duties of the position congenial, or likely to be well performed; and the result in some cases is suggestive in a measure of an attempt to make a sheep-dog out of a greyhound, or a retriever of a mastiff. Another important study with the same objects in view is the diathetic tendencies of a child, and the knowledge of these we chiefly gain from observing his parents and blood relations. It is well known, for instance, how unhealthy, as a rule, are the offspring of a gouty father and a strumous mother; and those who had the advantage of hearing the late Professor Laycock lecture on this subject can testify to the sagacity and truth of his observations and teaching. How many boys and girls at school have been harshly treated who would have been spared had the teacher possessed the requisite knowledge and training to recognise that what is often termed "dullness," "obstinacy," "temper," "nervousness," &c., are most frequently beyond the child's control, and should not be punished as faults, but regarded as congenital deficiencies and deformities which, by skilful treatment, may, and probably will, in time disappear. I think the time will come when the public will recognise the value of skilled medical advice in these matters, and also on another equally if not more important matter—namely, the probable result as regards mental and physical health of offspring likely to be produced by the union of persons possessing certain hereditary tendencies to one or other class of constitutional disease. If the importance of this were more widely known and appreciated it would in due time have a perceptible influence for good upon our national health and our average longevity; our asylums would have fewer inmates, and we should not in practice so frequently meet with cases of "debility," "neuroses," "spinal irritation," "skin diseases," &c., not to speak of the innumerable shades of morbid mental condition, which form the most intractable and disappointing class of cases that come under our care.

I remain, Sir, yours faithfully,

DOUGLAS W. ESHELBY, M.D.

Nov. 6th, 1882.

Mr. N. W. Davies.—Compliance with the request involves no responsibility of the kind mentioned.

Mr. Shuttleworth.—We regret we cannot find space for the reports.

## CASE OF IMPERFECT DEVELOPMENT.

To the Editor of THE LANCET.

SIR,—The following case of imperfect development occurred in my practice last week, and as it appears of somewhat an unusual nature, I send you an account of the same. The original has been sent to the museum of the College of Surgeons. The placenta was attached to the upper part of the child's skull, and took the place of any bone in that situation, and also of any dura mater, as the portion of brain which protruded, owing to a rupture occurring during birth, was destitute of that membrane. There were no fingers on the left hand, only a thumb; and the left leg completely twisted outwards. The child was born before my arrival, and I found it crying strongly. Although it was evidently a case of partial placenta prævia, there seems to have been but very little hæmorrhage at the time, although a week before the patient appears to have lost considerably. The mother is the wife of a strolling actor, and is slightly deformed from old hip mischief.

I am, Sir, yours faithfully,

Violet-bank, Lower Norwood, Oct. 27th, 1882.

JOHN B. HARRIS.

## THE OIL OF MALE FERN.

To the Editor of THE LANCET.

SIR,—The question as to whether the oil of male fern is a poison when administered in small doses is one by no means devoid either of interest to the practitioner or of importance to the public. In my opinion it must be regarded as such, at least in the case of individuals of a certain temperament—viz., the nervous.

In 1866 I recommended a friend—a thin, spare man, possessed of extreme pallor of countenance, and aged about twenty-three years—to make trial of the drug. He took but a single drachm, and that drachm followed, after the lapse of ten hours, by a tablespoonful of castor oil. The results were as follows:—Diarrhoea, nausea, vomiting, colonic spasms, and semi-collapse for about two days; nausea, a burning sensation at the epigastrium, and inability to stand erect for about a fortnight afterwards. A very slow and tedious convalescence. At this date—twenty-six years since taking the dose, please to recollect—the bare mention of the drug causes him to shudder, and to declare that he has still the smell of it remaining in his nose.

Was he not actually and veritably poisoned? Is he still, to some extent, suffering from the toxic influence of the medicine? Will he ever become perfectly free from that influence?

I am, Sir, yours faithfully,

Canterbury, Nov. 1st, 1882.

JOHN BEADNELL GILL, M.D.

Mr. C. Wilson.—We have no experience of the use of the preparation for the purpose named.

## TRACHEOTOMY TUBE.

To the Editor of THE LANCET.

SIR,—Will you kindly allow me to draw the attention of the profession in your columns to a new tracheotomy tube which Messrs. Maw, Son, and Thompson have manufactured for me. It is made of the new material, celluloid, is cleanly, light, and very smooth, and possesses a quality which is not found in india-rubber or metal—viz., the property of being readily moulded by immersion in hot water to any shape required.

Having recently performed tracheotomy in a case of malignant disease of the oesophagus, I found that the growth was pressing upon the trachea to such a degree that the india-rubber tubes became flattened. It occurred to me that a tube made of celluloid would be sufficiently firm to resist any pressure from without, and the result has so justified my expectations that I can confidently recommend them to the profession.

I am, Sir, yours faithfully,

Gay-street, Bath, Nov. 7th, 1882.

F. KING GREEN, F.R.C.S.

## "HAMAMELIS VIRGINICA."

To the Editor of THE LANCET.

SIR,—I have used a tincture of the above, supplied to me by Gale and Co., 15, Boulevard-street, Fleet-street, in numerous cases of hemorrhage during the last two or three years. A formula for a tincture is to be found in Squire's Companion to the Pharmacopoeia, 1830 edition, and I obtained a good deal of information as to its use from Dr. S. Ringer's seventh edition, p. 312. In a severe case of hæmorrhæmorrhæ occurring in the month of August the hemorrhage was satisfactorily controlled by the small dose recommended by Dr. Ringer.

I am, Sir, yours truly,

Rugby, Nov. 5th, 1882.

J. INGLEBY MACKENZIE.

# Introductory Address

DELIVERED IN THE

## UNIVERSITY OF GLASGOW,

To the Students of Medicine of the Session 1882-83.

By W. T. GAIRDNER, M.D.,

PROFESSOR OF MEDICINE IN THE UNIVERSITY, AND PHYSICIAN-IN-ORDINARY TO THE QUEEN IN SCOTLAND.

GENTLEMEN,—I appear before you to-day at the request of my colleagues, not, certainly, without a feeling of satisfaction and even pleasure in my task, but also with a most serious sense of responsibility. Only on two previous occasions has it fallen to my lot to address to medical students the very first words of exhortation at the opening of a new session—once in Edinburgh, in 1856, and once in Glasgow, in this university, but not in these halls, in 1866. When we consider that sixteen years have elapsed since the last of these occasions, and that during this interval almost all of my then colleagues in the Medical Faculty have either been taken from us by death, or have passed into an honourable retirement, the very facts themselves seem to raise the question, Where shall we all be after another sixteen years? And although I am assuredly not bound to answer this question, and have no personal misgivings leading me to despair of being permitted to labour for some years to come on your behalf, yet it cannot but be present to my mind that this *may* be the last occasion for me, as it is the first for some of you, on which words like those I have it in my mind to speak may remain to be spoken between us. Let us, therefore, strive together to make the present occasion one which we may look back upon, if God will, as tending to confirm in us whatever of good, honest purpose we are conscious of having devoted to our work in the past; and not devoid, also, of some new inspirations or glimpses of insight as regards the unknown future that is before you, and equally before all of us, your teachers. I am sure that I speak the mind of all of them when, in welcoming you anew to these benches, we add the expression of an earnest desire, or prayer, that we may also be enabled to perform our share in the duty aright, and that the good work done and the friendly associations formed during the session of 1882-83 may be of such a nature as to be an abiding influence for good over all the years to come.

In considering the materials before me for a new Introductory Address, it is impossible to avoid looking back for a moment on these two former addresses. I would fain not absolutely repeat myself, and yet there is much of what falls to be spoken which could only be spoken again in similar, if not identical, words to those already used. It would not be altogether impossible, perhaps, to commit this justifiable plagiarism without a chance of detection, on the present occasion. For introductory addresses are, like the occasions that give rise to them, soon forgotten, at least by all who are not immediately concerned in them. But I am not without hope that such reminiscences as cling to my own mind of these earlier addresses may be turned to account, not for the purpose of reproducing their ideas, but rather of inquiring how far the progress of the medical art has, in any degree, confirmed or controverted the impressions entertained of it by a teacher sixteen or twenty-six years ago. And with this view I intend, as soon as possible, perhaps in a few days, certainly some time between now and Christmas, to place at your disposal the whole of these addresses, including the present, so that you may at your leisure, if so minded, follow out with more full understanding and appreciation the few suggestions, imperfectly expressed as I fear they will be, called forth by the present occasion.

And while in this retrospective mood, I am reminded that only the other day we had set before us, in the shape of a leader in *The Times*,<sup>1</sup> and in connexion with the opening this month of the various medical schools in London, a singularly clear and luminous appreciation of the changes introduced into medical study and practice in England, as the consequence of the Medical Act of 1858; from which any-

mous, but not unauthorized, statement it may be admissible to borrow a few sentences as an illustration of our present position; keeping in view always that the writer of the article in question, well informed and thoroughly impartial as regards his own division of the United Kingdom, has had England, and apparently England alone, in view, in describing the state of medical education before 1858, and the changes gradually effected, owing to the legislation of that year. Were one at liberty, indeed, to guess (for everyone knows we can do no more) at the authorship of that particular article, to see with the mind's eye the Vulcan that forged the thunderbolt of Jupiter on that particular morning, I should be disposed to say that, judging from internal evidence alone, the brain that guided the hand that wrote that particular article was also one of the most active of those recently at work in elaborating the report of a Royal Commission appointed to inquire into the Medical Acts, with a view to their consolidation and amendment. If this be so, it gives, for us, an additional interest to the sentences of that article which I shall presently lay before you; and although it is by no means my intention to make this address in any respect a political or controversial one, it is certainly a fact to be noted that an Englishman, presumably well acquainted with the facts, and speaking of England, and for England alone, in the columns of *The Times*, should employ the following expressions as regards the state of medical education a year or two before the passing of the Medical Act of 1858, and yet a year after my first introductory address to medical students in 1856:—

"Five-and-twenty years ago, except in the case of the small number of men who graduated in medicine at Oxford or Cambridge with a view to consulting practice as physicians, the education of a medical student commenced by an apprenticeship to a licentiate of the Apothecaries' Company, which was then the chief source of the medical qualifications of general practitioners. The apprenticeship was rendered necessary by the Act of 1815, from which the Company derived its powers, and it usually commenced at about the age of fourteen years, so as to break prematurely into school education. The first year of the apprenticeship was often spent in the work of a surgery boy, varied by the preparation of medicines, and by the attainment of some knowledge of their properties. The later years were devoted to learning the business of conducting a medical practice, the art of talking to patients, and so forth; and, when the apprenticeship was concluded, a short term of hospital study formed a prelude to the single examination which, when passed successfully, permitted the candidate to work his will upon the sick under the protection of the law. Originally, the full term of five years' apprenticeship was served in the house of the master; but as the term of hospital study<sup>2</sup> was gradually extended from one year to nearly three, the two demands were found to consume an inordinate amount of time, and the last two years of apprenticeship were commonly remitted, and were suffered to form part of the period of hospital study. Even then the total period of professional as distinguished from general education extended over about six years; and, as the examination might be passed at the age of twenty-one, was usually commenced not later than fifteen."

I interrupt the quotation at this point simply to say that one has to go back a long way in the history of medical education in Scotland to find a state of matters at all resembling the one here described. We had our errors and deficiencies, no doubt, and to some of them I shall allude more or less distinctly before I have done; but at no time within my recollection, nor, I think, within the recollection of those who preceded me, and whom I remember as my own instructors, was it even possible in Scotland to mistake a "surgery boy" of fourteen, prematurely withdrawn from school in order to manufacture pills and potions, and run errands, and make himself generally useful in a "shop" where he was under indentures to an "apothecary," for a regular student of medicine. To whatever extent the apprenticeship system held its ground in Scotland twenty-five or even fifty years ago (and far be it from me to say that in the hands of such men as Abercrombie, and others like him, it was not a system capable of much good), it was always

<sup>1</sup> To a reader unaccustomed to the phraseology here employed, it may be necessary to explain that "hospital study" throughout this quotation corresponds to what in Scotland would be called regular medical study within the curriculum, whether in hospital or not. In the London schools, which are all attached to hospitals, this is well understood, but not so in Scotland.

controlled by a regular academic discipline, emanating mainly from the universities, but largely reinforced, I am bound to say, by the coördinate influence, and often rivalry, of some of the corporations in building up what is now called the medical curriculum. In Scotland, at the period here referred to, a medical student so-called, was rarely less than seventeen, or, at the very earliest, sixteen years of age; and he was bound at the very outset to constitute an *annus medicus*—i.e., to engage in an amount and kind of real study which effectually precluded the possibility of his being allowed to run wild as a "surgery boy," such as is alluded to in *The Times*' article; a type from which the Bob Sawyer, and Ben Allen of Dickens' well-known story was only a too natural outgrowth. I venture to claim for the Scotch medical student of twenty-five years ago, even while admitting many deficiencies in his education both general and professional, that he was (saving a few sad exceptions) for the most part not only bound over to learn, but really in earnest in learning, the scientific as well as the practical work of his profession; that he was not devoting days or years which should have been occupied by ordinary school training, to "the preparation of medicines, and the attainment" (by chance) "of some knowledge of their properties;" but that he was, as I hope and believe you are, seriously impressed with the need of really scientific training as a foundation, and actually carrying out such training in anatomy and chemistry, even during his first year. Moreover, it lies strictly within my personal experience in 1856, when I had already taught several classes of Practice of Medicine, some of them numbering more than 120, to declare that the type of medical student existing at that time in Scotland was one which it was quite easy and natural for me to address as an assembly, not of undisciplined schoolboys out of school, but as "gentlemen" preparing, not without the solemnity and gravity proper to men, for the great business of life. I will add that this has been my uniform experience of medical students as a class from first to last; and I appeal to the words of both my introductory addresses in proof of the fact. I affirm that it would have been practically impossible to use the words of these two addresses, seriously and sincerely, to a body of men in whom the Bob Sawyer element formed any considerable intermixture; and I claim for our Scottish system of university and other regular medical education whatever credit may accrue to it from that fact.

I now return to the quotation from *The Times*; but what remains of it, though most important to us, is very short:—"The Medical Act of 1858 introduced changes by which apprenticeship was abolished and the hospital course extended to four years, so that up to the age of seventeen school education might be continued. In order that the opportunity thus given might not be neglected, the student was required to pass an examination in general knowledge before he was permitted to commence his hospital career, and two professional examinations were instituted in place of one. The general result of the change was to occasion a marked advance in the intellectual status of students and of young practitioners. They lost, it is true, the familiarity with the management of a practice which apprenticeship was calculated to afford, and they lost opportunities of seeing many common forms of disease which are hardly severe enough to enter hospitals, but they gained more than an equivalent for these losses in their better education and their greater self-respect. They gained an advance in intellectual training which rendered them better able than their predecessors to grapple with the complicated problems so often presented by disease."

It thus appears that the changes introduced by the Medical Act of 1858 into English medical education were in a great measure those which had been in operation in Scotland long before, under the influence of our three teaching universities, and the medical schools associated with them in Edinburgh, Glasgow, and Aberdeen. Not that I wish you to infer that our state was all that could be desired, or even all that, under more favourable conditions of medical legislation, it might have become. The Apothecaries' Company, which I by no means wish to disparage, inasmuch as it has honourably striven to fill a position left to it by the other corporations, and thus to maintain the organisation of the medical profession in England, long enjoyed a practical monopoly for its licentiates of most of the offices in that division of the kingdom which formed the usual introduction to general practice. The Royal College of Physicians during the same period long declined to admit, even as licentiates, any but the graduates of Oxford or Cambridge, thus aiming at a

degree and kind of exclusiveness which effectually barred all possibility of its becoming the college of the medical profession. The Royal College of Surgeons, with a much more generally accessible, and therefore more popular, diploma, confined its whole attention to anatomy and surgery, under the theory that the other branches of a complete medical education were the province of the sister college, or of the apothecaries. Hence the anomaly of the "double qualification" which distinguishes England from almost every civilised country in Europe, for it involves the still more serious anomaly of the "single," or, as it may justly be called, the *half-qualification*, in virtue of which a man may enter into practice capable of performing operations, but entirely ignorant of medicines, and the diseases requiring their use; or, *vice versa*, capable of dispensing medicines, but almost entirely ignorant of anatomy and of surgical operations; and in either case far too much of a mere craftsman, far too little of an educated professional man.

The Scottish universities early perceived this anomaly, and long before the Medical Act of 1858 was passed, a regular curriculum of study had been instituted which was unquestionably (though still defective in many points) far more complete than anything hitherto attainable in Great Britain as a qualification for general practice. Not only so, but by a preliminary training in what we should now call the elementary biological sciences, botany, natural history, chemistry, comparative anatomy, and physiology, the mind of the student was opened to more than merely utilitarian views of his profession; the "surgery-boy" type, to which I have already alluded, was effectually eliminated, and replaced by a far higher kind of professional culture, founded upon a broad and generous estimate of the utmost that was then held possible between the ages of seventeen and twenty-one, to fit a man for the practice of every department of a profession which requires, and fully engages, all the energies of a well-disciplined intellect. It is true that in respect of what may be called scholastic training the Scottish graduates were often found deficient; the trifling modicum of Latin which in my time represented the whole of the non-professional culture required being a very poor substitute for the M.A. degree of Oxford and Cambridge, or any of the other insignia of the ideal academic man. True, also, that on the other side it was sometimes objected that the Scottish graduate in medicine was not sufficiently conversant with the details of compounding and dispensing powders and pills and mixtures, and, above all, draughts (at 2s. 6d. a piece) to be taken two, three, four, or five times a day; in other words, that he had not sufficiently mastered the technical details by which his neighbour, the English apothecary, was able to accomplish the great ideal of the developed "surgery-boy" type—the dispensing of immense quantities of "physic" in the most complicated prescriptions, to pass unquestioned down the willing throats of Her Majesty's lieges. But in spite of these two grave deficiencies, and perhaps many more in detail, of a more real character than either of them, the Scottish University medical graduate has struggled on, with every precedent and every national prejudice against him, to a position of great credit and influence in the sister kingdom; and what is far better than that, to a more and more elevated conception of his art and the sciences on which it rests. The cause of this gradual elevation of his ideal is that the universities, which did not wait for the Medical Act of 1858 to make a beginning, were, nevertheless, fully prepared to advance with the times, and carry out as rapidly as possible all the improvements suggested by that Act and by the Medical Council which it created. A Royal Commission, appointed in 1858, in accordance with the Universities (Scotland) Act, enabled them greatly to improve their internal organisation, just at the time when the Medical Act was initiating the revolution in English medical education and practice to which I have already referred. And now we are able to cite the very words of another Royal Commission, to show that our labours have not been in vain. "We readily acknowledge," write the Commissioners on the Medical Acts in 1882, "all that the Scottish Universities have done for medical teaching and examination, and we should hesitate to make any recommendation which, in our belief, would interfere with their usefulness or prosperity. We do not propose to interfere in any way with their teaching, nor do we believe that students will cease to recognise the cheapness and excellence of their teaching." These, gentlemen, are not the words of Scotmen, or of Scottish graduates; for on this Commission of eleven members there is only one

Scottish M.A., who is also a professor in Oxford, and one Scottish medical professor, who is also M.B. of the University of London; the others being a peer, a bishop, an eminent English judge, a distinguished statesman, an equally distinguished naturalist, and others quite removed from the least suspicion of any but a dispassionate judgment upon the facts presented to them in evidence, so far as we or you are concerned.

The two addresses which I propose to reprint along with this one will, I trust, convey to you some idea of the direction and scope of these advances in medical education; not perhaps, by any distinct and separate statement of them, but by the glimpses they afford of the aspirations, hopes, and fears on your behalf of one who has been associated with medical students, almost without interruption, since he was a student himself; and this, not in the class-room alone, but in the hospital, and at the bedside of the sick, for nearly thirty years. This double relation to you as your teacher, continued over so long a period, may perhaps be considered to give the weight which comes from experience to suggestions in themselves not otherwise remarkable or profound; at all events you will, I have no doubt, receive them as tending to show how much the mind and heart of a university professor are put into his work, and how much the labour of teaching is for all of us lightened by the secure conviction that we possess your sympathy in all honest efforts to raise the work to a higher level. I am also glad to be able to tell you, and especially the juniors among you, that the testimony of all my colleagues goes to show that an increasingly high standard is being attained, gradually, almost from year to year, and that in particular the studies of the first year in anatomy, biology, and chemistry, show, to a very marked degree, increasing thoroughness. As I attach the greatest possible importance to these studies, not only in respect of their actual details of fact, but still more as a training of the mind into the paths of observation and reasoned experiment, which lie at the very root of all safe and sound medical education, let me press upon you the importance of continuous diligence and zeal at this the very commencement of your studies. Be assured that the labour of acquiring even what is commonly called *practical* information and skill in your profession will be greatly lightened, and your success greatly aided, by application to what is, and must ever be, the only foundation of a medical art that reaches beyond the merest empiricism. And now that all these departments may, according to the arrangements of this, and I believe all the other Scottish Universities, be studied in the laboratory as well as in the class-room, you may be assured that all the benefits which, in the first of these addresses, I ventured to anticipate for the development of practical methods of teaching, will be yours. It is, indeed, the increase of these methods in every department of our work that is mainly characteristic of these latter years of our Scottish University medical education. New buildings, new arrangements, new apparatus, new instruments of research, are everywhere found necessary, not only to convey the old truths, but to interrogate nature directly as to what is and what is not truth. And this *habit of mind*, which is nowadays not less than essential for success in every medical inquiry, can never be so easily and pleasantly acquired as in the first year of your studentship, in the fascinating pursuit of biological research, whether in the animal or the vegetable kingdom. "Don't think, but try," said that mighty man of biological science, John Hunter; not that he meant to discourage thought or intellectual activity, for his own was of the most unresting character; but that in his opinion all intellectual energy should resolve itself into active work, in the way of experiment and observation. This habit, so different from that of the mere literary student, finding his inspiration and materials alike in the knowledge that is got from books, must be acquired as completely as possible before you come to engage in clinical studies, for it is only to a limited extent that we can, in these, afford you the means of acquiring it. How are we to teach you effectually the fleeting phenomena of disease, if you have not for yourselves investigated the corresponding phenomena of health? How instruct you either in the one or the other to any purpose unless you have systematically cultivated your own faculties of observation and experiment by active personal research?

In the second of the introductory addresses to which I have referred I used these words in characterising the existing state of the science and art of medicine:—"The art of medicine is at this moment in a peculiar position.

The day of *orthodoxies* is over; the day of *real science* is only just dawning." It is worth while to return to these words for a moment, were it for no other reason than to inquire if the dawn has been at all brightening into day since they were written. The sixteen years since these words were written have been years of immense activity in research, and very much of what has been done in them tends, at least, to fulfil the promise of a medical art of the future founded not on mere hypothesis, still less on dogmatic statements fortified by authority, but on accurate, continuous, and patient demonstrations of fact. In the first place, the art of diagnosis is constantly being improved by the introduction of new methods; and the basis of all these methods consists in this, that diseases hitherto quite obscure, or called only by conventional names corresponding to their most obvious symptoms, are being daily defined and rendered into much more exact conceptions in the light of an improved physiology and pathology, resting upon observation and experiment; so that what were formerly mere ancient names, surrounded by a halo of antiquity and traditional learning and skill, are now recognised symbols guiding the mind to well-understood lesions, as of the brain, spinal cord, heart, arteries, lungs, organs of special sense, and other well-defined points of the living economy, where, in many instances, the presence of the change, or lesion, can be actually demonstrated by such novel instruments as the sphygmograph and cardiograph, laryngoscope, ophthalmoscope, &c. I mention these newer instruments of precision, as they have been justly called, without prejudice to the much older and more established means which are now in the hands of every practitioner—the stethoscope, microscope, thermometer, and simple applications of chemical analysis—all of them employed in accordance with modern pathological investigations of a far more exact kind than any known to those great and wise men, from Hippocrates and Galen downwards to Hoffmann and Boerhave, from whom the art of medicine derives, or derived until the present century, the greater part of its current nomenclature of diseases. This great progress in the direction of realism in diagnosis is apparently quite boundless; for no one can tell, nay, no one can even conceive, how far the progress of a very accurate physiology and pathology, based upon physical and experimental science, may lead us in the years to come; any more than anyone could in these latter years, by mere inspiration or study, have anticipated the splendid researches of Pasteur, the triumphs of antiseptic surgery, or the discovery of Koch's tubercle bacillus.

The mention of these splendid achievements, mainly of the last twenty years, and the last of them only of yesterday (as it were) recalls the fact that it is not only, perhaps not even chiefly, through the perfection of diagnosis, that the medicine of to-day is advancing from dawn into daylight. The enormous labours, the multiplied and varied observations and experiments, that have been bestowed upon these modern researches, in the genuine spirit of exact physical investigation, show that the progress even of diagnosis, and much more of the prevention and treatment of disease, is coming to depend to a greater extent than ever before, upon that discipline of the mind which is to be found only among the consummate masters of physical science. Every day and every year removes us further from the period when it is possible merely to make chance hits in therapeutics, and so, by an individual happy thought, or particular prescription or nostrum, to compete with those who are investigating cautiously and experimentally the results of remedies in disease. The thorough investigation of remedies, in their action both on the healthy and diseased organisation, is proceeding at a rate that seems, I confess, sometimes to be almost too rapid for security, but which has resulted, and no doubt will yet result, in achievements not less remarkable than the advances in diagnosis. And here let me give in my adhesion, in passing, to every word of the admirable address delivered the other day to the students of the Veterinary School by my colleague, Professor Cleland.<sup>3</sup> Like him, I am not personally engaged in experiments on living animals, and have no reason to expect that I shall soon, or perhaps ever, be so engaged. But I hold it to be all the more on this account necessary to protest against a law under which neither the invaluable experiments of Pasteur on the bacillus of anthrax, nor those of Koch on tubercle, could legally have been performed in this country without

<sup>3</sup> Glasgow Medical Journal, November, 1882.

repeated special applications to the Secretary of State, which might with great probability have been refused, or unreasonably delayed. Punish cruelty by all means, and repress it by restrictive enactments, provided you can devise such enactments as will strike impartially at the cruelties of science and of sport; but for a Parliament which tolerates, or even encourages the latter to single out men of science, some of them the most distinguished benefactors both of mankind and of the animal creation, and to place them under ban, forbidding them the freedom of action that is conceded to all other men until they are proved to have done amiss, is to my mind one of the most monstrous and inconsistent, if not hypocritical, positions that any Legislature could assume.

The rapid progress of sanitary and preventive medicine during the last twenty-five years is a subject on which I might well detain you, were it not that I feel that this address has already run to a length sufficient for its purpose. Nor is it necessary, nowadays, to draw special attention to this point. For the progress here has not been from dawn, but from almost absolute darkness into daylight. Every newspaper, every monthly magazine teems with the popularised results of sanitary investigation. He that runs may read. And nowhere less than in Glasgow are we likely to be allowed to forget the importance of this line of investigation, or the many admirable results that have been brought to light by our excellent medical officer, Dr. Russell. The danger rather is, in my opinion, that feeling ourselves so well served, and at the same time so well represented in him, the medical profession at large will cease to interest itself in details which can be so easily handed over to a large and well-organised staff of public officers. This, I think, would be a great evil for us, not less than for the public. For preventive medicine, or the scientific study of the causes of disease with a view to their removal, is an integral part of the art of medicine in general, and cannot be withdrawn from the consideration of its professors without great injury to their function as healers. For these reasons, which I have always insisted upon in detail at every fitting opportunity in my own course of practice of medicine, I should be sorry to see the preventive medical service, or as it is called, the *sanitary* work of the medical profession, too completely specialised, and thus separated altogether from the rôle of private practitioner, as has been too much the tendency of late years. To you, as students, I would strongly recommend not to lose sight of either aspect of your future duties. Having acted as a public health officer for nearly ten years previous to 1872, I am able to speak from personal conviction of the valuable effect of such a career in educating the mind towards the recognition of some of the highest duties of the practitioners in the ordinary sense. And this education I shall hope to convey to you, in principle, even if I shall leave to others (as must need be) the development in your instruction of the daily increasing details which form the proper subject of a distinct sanitary course.

Gentlemen, I have done. All that remains for me is to wish you, on behalf of my colleagues and myself, a prosperous, animated, and a successful session. That will not be wanting, if you and we together approach our work in the right spirit. Be in earnest. Be diligent. Be modest and truthful. Help us, as we desire to help you, by mutual sympathy in our joint labours. Finally, *ora et labora*. Look for the blessing from on high. And if modern science seems, at times, to wean your minds away from God, look again, and look further and yet nearer, till in the reign of law you can perceive a truly divine order; in nature a living force behind nature; in the mystery of your own will the faint image of a higher will than your own, neither less nor more mysterious in its essence; in the endless descent of species, whether by evolution or otherwise, the infinitely multiplied reflection of a relationship to Him, who, while He is the Father of our spirits, and the framer of our bodies, is also "nigh to everyone of us," the Father of all the families of the earth, from everlasting to everlasting.

Hughes, Archibald Jacob, Rawdon Macnamara, E. Mapother, H. Minchin, E. Stamer O'Grady, G. H. Porter, B. W. Richardson, W. Roe, P. C. Smyly, W. T. Stoker, William Stokes, W. Thomson (Hon. Sec.), R. L. Swan, Jolliffe Tufnell (Hon. Sec.).

## THE UNITY OF SURGICAL PRINCIPLES IN WOUND AND FRACTURE TREATMENT.<sup>1</sup>

By SAMPSON GAMGEE, F.R.S. ED.,  
CONSULTING SURGEON TO THE QUEEN'S HOSPITAL, BIRMINGHAM.

WOUNDS and fractures are alike interruptions of continuity,—the former of the soft, the latter of the hard parts. They differ in the density of the tissues involved, and proportionately in the time required for reunion; but they are essentially similar in processes of repair and principles of treatment. In wounds and fractures, division of tissue is the essential fact which gives rise to a common chain of events—mobility, disordered innervation, and effusion,—which become causes of ulterior pathological results, if their development be not checked by proper treatment. The indication, common to the vast majority of wounds and fractures, is to bring the severed parts together and keep them so during the process of repair. How that indication shall be fulfilled—what peculiar appliances are demanded by injuries in particular situations, and by such complications as contusion, hæmorrhage, and inflammation,—are questions traversing the whole domain of surgery: fit themes for a treatise, only admitting of cursory treatment in a paper for an evening's discussion. It will be my endeavour only to select for comment those salient principles and points of practice on which agreement is most to be desired and nearest of attainment.

Firstly, as to the reduction of fractures of the limbs; that should be immediate, and maintained with the nearest practicable approach to immobility, a rule of practice of which no other in surgery admits of fewer exceptions. In selecting from amongst the numberless contrivances for maintaining immobility, preference should be given to those which admit of accurate moulding to the limb, including the joint above and below the seat of injury. It is beyond question that, with wood and iron splints, many surgeons have for generations achieved excellent results in fracture treatment; but, for comfort to the patient and freedom from complications, moulds are best; they can be constructed with a great variety of materials—plaster, gum and paraffin, millboard (plain or soaked with dextrine), gutta-percha or pro-plastic felt. The last-named and dextrined millboard are, I think, the most handy and efficient; but, where all are good in principle, choice may well be left to the predilection which grows out of individual experience. Whatever splint or mould be used, let it be well padded, and I know no pads equal to those made with absorbent gauze and cotton, which possess practically indestructible elasticity. The materials of which bandages are made, still more the method of bandaging, are of the first importance. Uniform elastic compression powerfully contributes to preventing muscular contraction, and *pro tanto* securing immobility. It prevents extravasations, and, when they do occur, promotes their absorption. I employ pressure in the treatment of all fractures, with perfect elastic padding, light, yet decidedly compressive, smooth bandaging, without ruck or reverse. It is many years since I used one of the unbleached calico bandages common in most hospitals. Preference should be given to these soft, bleached, absorbent bandages. A depth of two inches is the handiest, the rapid spiral the most convenient, comfortable, and efficient, mode of application. In bandaging a leg, for instance, having previously padded it, a couple of circular turns are made just above the ankle. The roller is then carried along the dorsum of the foot, and a circular turn made around the roots of the toes. With a few figures-of-8 the foot, including the heel, is covered; the roller then carried spirally along the front of the leg to the knee, here made fast with a circular turn. Alternately ascending and descending figures-of-8 complete the elastic investment. The method is applicable, with trifling variations of detail, to all parts of the body. Whenever practicable, suspension will be found of the utmost service as an addition to the means of maintaining immobility. The suspension of a limb in two or more loops of bandage or leather is not what is here meant; that is comparatively fixed elevation, of unquestionable advantage for position, but not a perfect swing; for this a fine cord is even better than a chain. The greater the motility of the suspending medium,

<sup>1</sup> Read before the Medical Society of London, Nov. 6th, 1882.

the more completely does it oscillate and exhaust any motor power communicated to the limb; in other words, the fragments of a suspended broken limb, once perfectly adjusted, can be kept at rest in direct proportion to the perfection of the swing.

Another form of suspension, different in principle and mode of application, but still very useful, is that of suspending a weight to a limb. It overcomes muscular contraction by steadily exhausting it, and alone, or in combination with moulds and pressure to an injured part, is of great service in maintaining immobility. Assuming so much conceded for the treatment of a simple fracture, agreement would probably be less complete, if a fracture complicated with swelling, sanguineous or inflammatory, were in question. But in such a case, no less than in the simple one, should reduction be immediate, with elastic compression, absolute immobility, and oscillatory suspension. Digital compression of the main artery will assist in promoting absorption. In a very few hours the outside of the apparatus becomes loose, and its elastic construction admits of fresh padding and compressive bandage, without disturbance of parts, and with unfailing benefit in promoting absorption, checking inflammation, and consolidating repair. The additional complication of a wound or a bleb makes no substantial difference; given a compound fracture, only let the fragments be immediately and accurately adjusted, the wound closed with all necessary provision for perfect drainage, the limb immobilised compressed and swung, and, in the vast majority of cases, the fundamental indication will have been carried out, reducing the compound to a simple fracture, and treating both on identical principles.

If a simple fracture, say of the clavicle because it admits of easy observation, be not at once immobilised, material is thrown out between and around the broken ends of the bone the deposit thickens, the part becomes hot and painful. Such a condition is best seen in those, happily, rare cases in which a fracture of the clavicle goes for some days undiagnosed. Immobilise the limb and the callus vanishes, all the more rapidly if compressed under an elastic pad. Given a flesh wound in most parts of the body; if the edges be at once accurately brought together, and kept so, provision made for deep and surface drainage, and immobility maintained, direct union takes place, all the more surely if the part be kept in a position to favour venous return and prevent arterial afflux. Here, again, perfectly smooth elastic compression is of the greatest service, not merely in maintaining contact of the deeper, as well as of the superficial, lesion, but in restoring the balance between elastic resistance and blood pressure, which is the normal condition of living parts. Let a flesh wound, like the one we have just been considering, not be accurately adjusted; let it be treated with water dressing or a poultice, with the limb dependent and not immobilised. The edges become tumid, the wounded surface discharges and stinks, the surrounding skin is red, tumid, and painful. In this state, raise the limb to empty it of its blood, approximate the edges, resort to elastic compression and immobilisation, swelling and pain vanish as if by magic, and healing proceeds, just as in the case of the fracture with swelling which we were considering a few minutes ago. A fracture with a wound complicating it, the condition generally known as compound fracture, will be found amenable to treatment on the principles enunciated with the happiest results.

My remarks have hitherto been directed to injuries of the limbs. Their truth and practical value are equally well, if not better, illustrated in injuries of the head, with some modifications rendered necessary by the condition of parts. In a fracture of the vault of the cranium without wound, the great indications of rest and prevention of extravasation are fulfilled by keeping the patient in comparative darkness, in the horizontal position, with an ice-cap. No wounds do better than scalp wounds under dry dressings, elastic compression, and a minimum of subsequent interference. An adaptation of the same principles, according to the exigencies of particular cases, will ensure success in the treatment of a large proportion of compound fractures of the skull. The question of trephining is one of special and exceptional interest, to which it would be here impossible to do justice. But as I have no wish to shun difficulties, and to restrict the scope of discussion, I may briefly state that there are very few cases in which I consider trephining justifiable in fractures of the skull. I have practised it, and seen others do it, with happy result; and I can conceive of cases in

which I should not only trephine, but be prepared to incise the membranes and the substance of the brain, to fulfil local indications of effusion and compression. But if we go back to the early days of this controversy, and trace it down to our own time, I am clearly of opinion that more people have owed their death, than their life, to the trephine.

To ensure absolute rest in wounds and fractures, immobility should be secured to the utmost practicable extent, while the reparative process is going on; but no longer. Every surgeon knows how much mischief results from rest too long persisted in. The experience only affords another illustration of almost every truth, psychical and physical; carried to extremes it becomes a vice. With this reservation, the practical application of which must depend upon the exigencies of particular cases, immobility is one of the most powerful factors in surgical therapeutics. A corollary of that proposition is infrequent dressing. On this point the agreement of surgeons at home and abroad has grown very manifestly during the last few years. Whatever the nature of the injury, it is scarcely possible to be too accurate and complete in first dressings. Then watch the thermometer and the pulse, the patient's expression and the state of the skin; and so long as those cardinal indications point to safety, dress as infrequently as possible. To this end absorbent dressings contribute materially, and if they be not sufficient to ensure perfect drainage, one or more tubes may be employed for the purpose. By keeping them long, and carrying them out through the pads, it is easy to collect the discharge in a pad lightly placed over the end of the tube, so as to combine frequent removal of discharges with immobility of the apparatus.

Experience proves that the more absolute the immobility, the more evenly the limb is compressed, the closer attention is paid to position, proportionately less are irritation, vascular turgescence, and consequent effusion. The healing part shrinks as it consolidates, and dries in direct proportion as its nervous and vascular life is controlled. "That under dry and infrequent dressings, absolute rest, physiological position, and elastic pressure, most wounds and fractures heal," is a proposition which I have striven to defend since I formulated it years ago. The argument so far has been in the same direction, and that because experience only confirms its soundness.

(To be concluded.)

## NOTE ON THE USE OF BOROGLYCERIDE IN THE TREATMENT OF WOUNDS.

BY HENRY A. LEDIARD, F.R.C.S. ENG. & M.D. ED.,  
SURGEON TO THE CUMBERLAND INFIRMARY.

ON March 19th of this year I was some distance from home, consulting with Dr. Walker, of Stapleton, in this county, and he mentioned to me that a new antiseptic (boroglyceride) was creating some stir in Germany, and offered to provide me with some if I would use it and record my experience. Accordingly a few weeks later I received four ounces, which were dissolved in water and used in the strength of 1 to 20 and 1 to 40. In appearance boroglyceride is like large cakes of isinglass, of the colour of gum acacia, sticky as toffee, and has a slightly warm taste of indefinite and transient character. In solution it is colourless and almost tasteless.

We are now in possession of a few facts in reference to the use of this new antiseptic as applied to wounds, many of which have been treated with it, but owing to the supply from Dr. Walker having scarcely kept pace with the demand, the trial has not been as complete as could have been desired. A case of Syme's amputation for ankle-joint disease was treated with boroglyceride from the first—i.e., the flaps were washed with the solution, and the stump wrapped in lint steeped in 1 to 40 solution; the subsequent dressing consisted in washing out the cavity and using lint as before, the result being as excellent as, but not more excellent than, I have seen in similar cases treated with dry lint. The stump kept sweet to the nose, but the drainage-tube and pus squeezed from the stump were not so. It is probable that we used the solution

too sparingly; and allowance must be made for this, for occasionally we had to wait for the arrival of a fresh supply. Another case of railway smash of the foot (Syme's amputation also) which was not healing kindly (Listerism having been relinquished on account of putrefaction), was treated with boroglyceride, and although healing was neither interfered with nor accelerated, yet smell was unquestionably kept down. Several wounds, the result of either accident or surgical operation, have also been treated with boroglyceride with satisfactory results, and the conclusions I have arrived at so far are as follows: For open wounds or wounds with open cavities boroglyceride in solution will be found to be a non-irritating and powerful antiseptic, in no way interfering with natural healing processes, and in no degree troubling the skin around a wound; but where shut cavities exist, as in stumps after amputation, although syringing with the solution be adopted, yet the discharge collecting within is not kept sweet. I feel sure that much remains to be done to develop the use of this new antiseptic, which, on account of its non-irritating properties, will prove of much value in the treatment of wounds. To claim for any antiseptic a value beyond one's experience would be to court distrust, and I prefer to speak hopefully rather than positively.

Mr. Barwell's paper in THE LANCET of May 13th certainly supports our experience of the value of boroglyceride, but we have not succeeded in preventing rises of temperature, any more than we have succeeded in obtaining union without one drop of pus, neither have we seen remarkable results as to healing by first intention; in fact, the results may seem to be *nil*. I think the use of stronger solution than 1 to 40 or 1 to 20 may be tried, and the lint around the wound should be kept constantly moistened with the solution. As far as I am aware boroglyceride is innocuous, a matter of great moment, when one recollects how many patients have been poisoned by doses of carbolic acid by inadvertence, how many untoward symptoms have been put down to the use of the carbolic spray and absorption of carbolic acid.

I hope on a future occasion to add more to this brief note, which must conclude with an acknowledgment of thanks to Dr. Walker, who manufactured the boroglyceride himself.

Carlisle.

### THE DIFFERENTIAL DIAGNOSIS BETWEEN HYSTERICAL PARALYSIS AND POLIO- MYELITIS ANTERIOR.

By A. HUGHES BENNETT, M.D.,

PHYSICIAN TO THE HOSPITAL FOR EPILEPSY AND PARALYSIS,  
REGENT'S-PARK; AND ASSISTANT-PHYSICIAN TO THE  
WESTMINSTER HOSPITAL.

IN the experience of every practitioner there must have occurred cases of paralysis in women upon which he has been called upon to decide whether the affection was due to serious organic disease of the nervous system, or to that more protean disorder to which we give the name of hysteria. In many such instances there is often the greatest possible difficulty in arriving at a satisfactory conclusion, and the perplexity of the medical attendant is proportionate to the responsibility he assumes in expressing an opinion, and the important issues upon which his verdict depends. That grave errors in judgment on this complicated problem have frequently been made, must be within the knowledge of all, resulting in misfortune to the patient, discredit to the profession, and a triumphant harvest to the charlatan.

Polio-myelitis anterior, or, as it is more commonly called, "infantile paralysis," is more especially liable to be confounded with hysteria, as the symptoms and progress of the case are very similar in both. The paralysis resulting from this serious organic disease of the cord attacks the adult, both in its acute and chronic forms, much more frequently than is generally believed. It is obvious that to make a clear distinction between these two disorders is of the highest importance, as the treatment suitable for the benefit of the one would be useless, or even injurious, if applied to the other. A consideration of this question appears at the present time to be worthy of discussion, as recently there has been a revival of certain energetic measures in the treatment of paralysis of a supposed func-

tional and emotional origin; and Drs. Weir Mitchell, Playfair, and others have recorded successful cases of great interest and importance. Although it is admitted that certain procedures were followed by the most satisfactory results when employed by competent physicians, in properly selected cases, it must equally be granted that the same treatment would in different instances be followed by the most disastrous effects. The writer has not infrequently seen young women condemned to a couch for years, supposed to be suffering from spinal or uterine affection, which a little energy and determination on the part of the physician would have cured in a few weeks. On the other hand, not less often has he met with unfortunates who were scoffed at and otherwise ill-treated as being nervous and hysterical, or imagined to be exaggerating or feigning disease, when in reality they were suffering from an organic lesion of the nervous system. This confusion has arisen from the extreme difficulty in many cases of accurately diagnosing between paralysis, arising on the one hand from organic degeneration of nervous structure, and on the other as a result of emotional or so-called hysterical causes. It is assumed in text-books and by the profession generally that the differentiation between these is easily defined, but as a matter of fact even when the greatest care is taken this is not always the case, and after the fullest investigation much doubt remains.

With the view of illustrating this position let us take a case which not infrequently occurs in practice. A young woman suddenly or gradually becomes paralysed in the lower extremities. This may, in a few days, weeks, or months, in different cases, become complete or may remain partial. There is no loss of sensation, no muscular rigidity, no cerebral disturbances, or any affection of the bladder or rectum. The patient's general health may be robust, or it may be delicate. She may be of emotional and hysterical temperament, or, on the contrary, of a calm and well-balanced disposition. At first there is no muscular wasting, but as the disease becomes chronic the limbs may, or may not, diminish in size. The entire extremity may be affected, or only certain groups of muscles. Finally, the disease may partially or entirely recover, or may remain almost unchanged for years.

With such a clinical picture before us we have to ask, What is the diagnosis of such a paralysis? The description applies with equal fidelity to either hysteria or polio-myelitis, and by depending on symptoms alone it is in such doubtful cases that the decision of the question seems to depend on the accidental fancy of the medical attendant, and which so frequently results in an erroneous view being taken of the case. It is granted that the problem is a difficult one, and even a careful analysis of the symptoms does not appear greatly to assist its solution. The patient when attacked with the paralysis may be in perfect health, or the reverse; she may, or may not, be hysterical; there may be some assignable cause, or not. In all these circumstances the loss of motion may be either due to polio-myelitis or hysteria, as the former occurs with equal frequency in the robust and in the delicate, and the latter as often appears in apparently the most healthy persons as in the most nervous; the first is as likely to be present in hysterical subjects as in the reverse, and the second may follow a cold, injury, or other supposed origin of organic disease. In short, although it is true that hysterical paralysis frequently occurs in persons evidencing other nervous or emotional symptoms, these are by no means necessary to establish the diagnosis, as some of the most intractable forms of this affection have occurred in women of apparently phlegmatic temperament and well-balanced minds. Again, polio-myelitis is as likely to attack the hysterical subject as any other, and thus further complicate the inquiry. The paralysis appearing suddenly, or very gradually, applies equally to polio-myelitis or hysteria. As in the acute form of the first, the loss of motion may ensue in a few hours, and in its chronic form it may proceed very slowly and insidiously. In both the process may be partial or complete. It may attack one or more limbs, or only part of an extremity; indeed, special muscles, or irregular groups of these alone, may be affected. All these particulars equally apply to both forms of paralysis under consideration. In each the sensibility may be intact, the intelligence and special sense unimpaired, and the functions of the rectum, bladder, and other organs of the body healthy. If muscular atrophy existed to a marked extent at an early period of the disease we might exclude hysteria, but in many instances in this respect there is

nothing definite to be observed. The limbs in both forms of paralysis may for a long time appear of natural size. Muscular wasting, if it exists, may be obscured by an increased deposit of fat, and the hypertrophy of other structures. Again, if paralysis has existed for any length of time, the limbs may become smaller, not necessarily due to degenerative atrophy, but to simple emaciation from functional disuse. Thus, as in paralysis resulting from both hysteria and polio-myelitis, the symptoms and general progress of the disease are in many cases identical, it becomes a serious practical difficulty to definitely determine whether in a given case answering to the description already detailed, it is due to degeneration of the anterior cornua of the cord, or to that less formidable affection, hysteria.

To solve the problem, as in other branches of medicine, we must not depend on symptoms alone, but, as far as possible, should bring physical phenomena to our aid for the accurate determination, demonstration, and measurement of facts. Exactly in proportion as we thus supplement our senses, so do our powers of precise research and investigation succeed. Although important advances have been made in other fields of medicine by the utilisation of optics, acoustics, and other practical sciences, as evidenced by the employment of the ophthalmoscope, speculum, stethoscope, thermometer, &c., in diseases of the nervous system such methods of exact inquiry have hitherto been conspicuous by their absence. In recent times, as this want has been appreciated, endeavours have been made to supply the demand. The most successful of these is the employment of electricity as a diagnostic agent; and although our knowledge of its properties is not as yet fully developed, we have even now at our disposal such information on the subject as proves of invaluable service in the differentiation of many nervous disorders. It has already been pointed out that by symptoms alone we are not able, in many cases, to distinguish between paralysis resulting from organic disease of the anterior cornua of the cord and that due to hysteria. When we turn to physical signs, we find that there are at least two which give us definite information on the subject. These are—(1) the reflex actions following cutaneous irritation or percussion of tendons, and (2) the effects of electrical stimulation.

1. *The Reflex Actions.*—When polio-myelitis involves any reflex arc, the reflex motions associated with the track interfered with are destroyed. In the case, therefore, of paralysis of the lower limbs, resulting from this disease, all the cutaneous and tendon reflexes are absent. In hysterical paralysis, on the other hand, these phenomena are not abolished. They are usually normal, and not seldom are actually exaggerated in degree, so that not only are those which naturally exist much increased in intensity, but new reflexes not found in health are developed. Here, then, is a marked distinction between hysteria and polio-myelitis. Although this rule applies generally, it must be admitted that it is not without exception. Reflex acts vary somewhat even in healthy persons, and in rare instances have not been obtainable. Again, it is just possible that in degeneration of the anterior cornua certain parts of their substance might be preserved, and although paralysis existed, certain reflexes might be elicited. In hysteria also the reflexes are sometimes absent for reasons not easily explained. Such cases, however, are extremely rare, and the general law holds good that in paralysis from polio-myelitis the reflexes are impaired or abolished, while in that from hysteria they are normal or increased.

2. *The Electrical Reactions.*—These are for the most part definite and conclusive. In acute polio-myelitis the excitability of the affected nerves is very rapidly lost, so that in from a week to ten days after the onset of the paralysis the response is altogether abolished to the electric stimulus. Very soon afterwards the muscles are affected, and then ensues all the characteristic quantitative and qualitative changes met with in neuro-muscular affections. In the chronic forms of the disease the same takes place, but in a more gradual and progressive manner. In hysterical paralysis, on the other hand, the electrical reactions remain practically normal. In some cases there may be quantitative increase of response, indicating hyper-excitability of the nervous system, but these changes are slight in degree, and there are never qualitative alterations. In very chronic cases also, in which the patient has been bedridden for years, there may be quantitative diminution of response due to prolonged disuse of the muscles, or to increased resistance to the current from an augmented deposition of subcutaneous fat as the result of

want of exercise. In such cases the loss is never complete, and the change is one of degree only, and not of character.

Thus in electricity we have an agent which enables us in the large majority of cases to detect with accuracy and certainty between polio-myelitis and hysteria, and, so far as my own experience has gone, I have never met with a case of the former which did not present some characteristic abnormal reactions, nor an instance of the latter in which these were developed.

It is to be observed that great care and much dexterity and experience are necessary for profitable electrical investigation. It cannot be exactly asserted that an expert alone is necessary for this purpose, but certainly it cannot be satisfactorily conducted except by those who, through knowledge and practice, have overcome the technical and manipulative details necessary for its successful performance. The system of wildly dabbing sponge electrodes on the skin without a definite method, is absolutely useless as a means of deducing trustworthy diagnostic data, and it is the popular use in this way which has hitherto been so fruitless and brought a valuable physical agent into discredit. A novice, ignorant of the use of the stethoscope, would hear little or nothing on applying it to the chest, and still less would he deduce those important conclusions which the experienced physician would recognise. Precisely in the same way is electricity a means towards an end, which can only be put in successful operation by a practical knowledge of the agent employed, with dexterity and experience in its administration.

It would be out of place here to describe either the method of procedure or the particulars of the reactions found in the two forms of paralysis under discussion. These have elsewhere been considered in full detail.

The general conclusions to be drawn from the foregoing remarks are:—(1) That, judging from the history, symptoms, and progress of the case, in a large number of instances it is difficult or impossible to diagnose between paralysis from hysteria or from polio-myelitis; (2) that a correct differentiation between them is of the highest importance, as the treatment successful in the one is useless or may be injurious in the other; (3) that in order to arrive at a true diagnosis, we must as far as possible apply physical agents in their investigation; (4) that in the diseases under consideration the conditions of the reflexes, resulting from physical manipulations, afford us valuable information, although open to certain exceptions; and (5) that electricity supplies us with an agent which, in the large majority of cases, will definitely enable us to correctly decide whether a given paralysis is due to organic disease of the anterior cornua of the cord, or to that affection to which we apply the term hysteria.

## ON BONE-SETTING (SO-CALLED).<sup>1</sup>

By R. DACRE FOX, F.R.C.S. EDIN.,

SURGEON TO THE MANCHESTER SOUTHERN HOSPITAL, SURGEON TO THE MANCHESTER POLICE FORCE, CHIEF MEDICAL OFFICER TO THE MANCHESTER, SHEFFIELD, AND LINCOLN RAILWAY, ETC.

THIS is the first time in the history of the British Medical Association that so-called bone-setting has been seriously discussed, and I think it is matter for congratulation that we have at last set ourselves impartially to examine the practice, notwithstanding that it is almost exclusively employed by a class of persons who are without our pale. The literature of bone-setting is scanty. Dr. Wharton Hood's handbook, giving an account of the late Mr. Hutton's method of setting free stiff limbs, is, so far as I know, the only attempt at a systematic exposition. There are, in addition, some papers scattered through the various journals, by Mr. Adams, Mr. Howard Marsh, and others, stating their opinion as to what cases are most likely to be benefited by the forcible bending of joints, and giving instances of ill results that have followed such treatment in unsuitable cases. For nearly three years I was assistant to the late Mr. James Taylor, M.R.C.S., of Whitworth in Lancashire, the last direct descendant of a family that had practised

<sup>1</sup> Abridged from a paper read at a discussion before the Surgical Section of the annual meeting of the British Medical Association at Worcester, 1882.

bone-setting in that village for more than two hundred years, and I think I may perhaps be able to throw some light on the subject of this discussion.

Much misconception exists as to the practice of bone-setters; many of the methods of treatment popularly attributed to them have no other existence than in the imagination of ignorant patients, whose stories we as a profession are perhaps rather too ready to believe. It is certain that some families—notably the Taylors, Huttons, and Masons—have by their manipulative and mechanical skill justly acquired a great reputation. In what has their practice consisted? First, in the treatment of fractures, recent dislocations and sprains; secondly, in the cure of stiff joints, resetting of fractures, and correction of deformities. The general impression in the profession appears to be that the bone-setter's art consists of nothing more nor less than the forcible and reckless "cracking up" of stiff joints so as to make the lame man walk as if by a miracle. The practice at Whitworth was a large one, furnishing constant employment for at least two active men, and consisting chiefly of the cases I have mentioned. Speaking from memory I do not believe that fifty joints of all sorts were "cracked up" during the time I was there; but it was not an uncommon event to have to put up half a dozen fresh fractures and twice as many recent sprains in a single morning. In the North of England the origin of nearly all the men who are fairly good at bone-setting can be traced to the Whitworth surgery, and while, so far as I know, the Taylors in their various settlements at Whitworth, Todmorden, Lockwood, and Oldfield Lane were the only qualified surgeons who practised bone-setting; amongst the hills and dales of Lancashire, Yorkshire, and the Lake district, there were many who did so without being qualified, some of whom, I must in all fairness say, put up fractures uncommonly well. But apart from the legitimate credit they have won by the skill displayed in their handicraft, they owe some of their success to the carelessness or indifference of the general body of practitioners, who are apt to overlook little injuries which often become very painful and troublesome. It sometimes seems to me that it is beneath the dignity of the ordinary practitioner to employ any active treatment whatever for a sprain. It is hardly fair then to gauge the work of bone-setters solely by their method of treating diseased joints (probably the most unsatisfactory class of cases in the whole realm of surgery), but we ought also to take into account the patience and skill they display in the treatment of injuries for which they are not unfrequently consulted by the patients of qualified practitioners. I have no desire to hold a brief for every idle fellow who calls himself a bone-setter, but I am anxious to give credit where credit is due, and to explain that the art of bone-setting is not what it is often thought to be, a mere mixture of charlatanism and good luck.

I purpose chiefly to consider that class of cases to which Mr. Adams and Mr. Marsh have more particularly referred. Dr. Hood (*loc. cit.*) has made out a somewhat extensive list of causes for stiff or weak joints, but I think he had in his mind rather what was *likely* to come to the bone-setter than what actually did come. From my own experience I should classify weak joints as follows:—

1. Those that have become stiff from enforced rest.
2. Those that have become stiff from chronic disease.
3. Joints stiff from injury to the bones entering into their formation.
4. Joints stiff and weak from sprains, including displacement of tendons and partial luxation.

Apart from the previous history of the case, and the evident existence of constitutional disease, there are some external appearances which help to distinguish cases and to afford indications for treatment, and of these the bone-setters have learned by experience to avail themselves.

1. In the first class I have mentioned, the stiffness of the structures about the joint impeding its movements is the result of purely mechanical causes, is in fact simply due to prolonged disuse. No cause for functional activity exists, and consequently the elasticity, the flexibility, and power of adaptation to movement in the parts about the joints not being required, they become stiff and rigid. No degenerative changes, however, take place, and they are capable of being recalled into activity unimpaired. In such a joint the bony points and the outlines of the tendons and ligaments about it, seem unnaturally prominent, probably from absorption of the adipose and connective tissue; the rigid ligaments impart a sense of hardness, and if the limb be flexed to its

utmost it shows considerable resiliency. Such joints may, I believe, be "cracked up" without fear of consequences, and this constitutes one of the successful operations of bone-setters. My own recollection carries me back to some apparently almost miraculous results. I am convinced that *suddenness* ought to be insisted upon in doing this; the advantages derived from it being, I believe, mainly due to the fact that it is less likely to set up any irritation in the joint than the "dragging" of gradual extension.

2. In the next class of cases, in which stiffness is due to degenerative changes, the external appearances are exactly reversed, the outlines of the joint are more or less gone. In these cases, no matter the character of the disease, manipulative interference is positively vicious; and while it is in them that ignorant bone-setters do so much mischief, the better informed, by the use of splints and well-applied pressure, are highly successful in their treatment.<sup>2</sup> I am sorry to say very many cases of this kind come to bone-setters which have not been properly treated before, owing to their not having been recognised, especially hip-joint disease.

3. In the third class of cases, in which a fracture has taken place into the joint, causing stiffness, the condition is due to disturbed relationship of the bones from faulty setting, and is recognised by comparison with the bony landmarks of the sound limb. In these cases forcible treatment does good, though of course the result is in proportion to the amount of bone-displacement, but it should be supplemented by passive movements for some time. In joints stiff after diagonal fracture through the condyles of the humerus, so common in children, I have seen many most gratifying results; one in a boy about twelve years old, whose elbow had been stiff three years, is especially impressed upon my mind.

4. In the fourth class of cases, and those to which I would draw particular attention, I include lameness and weakness, the result of the various forms of injury, which we group together under the general term "a sprain." I affirm most unhesitatingly, from an experience of some hundreds of cases, that nothing has done more to lower the prestige of regular practitioners, and to play into the hands of unqualified bone-setters, than the way in which so many practitioners tamper with a sprained joint. Sprains, of course, vary greatly in severity; they may be broadly divided into two kinds, of which one consists merely of a temporary over-distension of the parts around a joint, which rest and anodyne applications soon cure, while the other involves pathological results of a much more serious nature. A *severe* sprain is the sum of the injuries that the parts in and about a joint sustain, when, by their passive efforts, they exercise their maximum power of restraint to prevent luxation. Under such conditions I conceive the following changes to take place in the integrity of a joint. In the case of the synovial membrane, temporary hyperæmia accompanied by pain, and some slight effusion into the cavity of the joint. In the case of the tendons, overstretching and loosening of the lining membrane of their sheaths, more or less disturbance to the adjacent cellular tissue forming the bed of the tendon groove, and hyperæmia with exudation of plastic fluid, subsequently forming adventitious products. In the case of the non-elastic fibrous ligaments—firmly attached at either end to the adjacent periosteum—overstretching, mostly involving partial rupture, with swelling, softening, and disintegration of their structure. It is beyond the purpose of this communication to draw attention to the plan of treatment adopted by bone-setters under these circumstances; it is, however, described in a paper of mine, of which an abstract is given in the *British Medical Journal* of Sept. 25th, 1880. The stiffness of a sprained joint is *partial*. The surface is generally cold, and more or less œdematous, and each joint has one particular spot in which pressure causes acute pain; the bone-setters have learned by experience the situation of these spots, and this fact has done more than anything to strengthen the popular faith in their intuitive skill; they certainly form an important guide to treatment, since they indicate the seat of greatest injury to the ligaments and point out where their power of passive resistance has been most severely tested, and where adhesions are most likely to have formed. Dr. Hood, in his record of Mr. Hutton's practice, has enumerated some of these painful spots; the chief of them are as follows:—

1. Over the head of the femur in the centre of the groin,
- <sup>2</sup> Rheumatic cases sometimes do well for a time, but invariably relapse.

corresponding to the ilio-femoral band of the capsular ligament (which is most severely stretched when the thigh is over-extended, as when the trunk is flung violently backwards, the commonest cause of a sprained hip).

2. For the knee-joint, at the back of the lower edge of the internal condyle—in other words, at the posterior border of the internal lateral ligament, where it blends with Win-elow's ligament, and where the semi-membranous tendon is in intimate relation with it. These parts suffer most because, as Mr. Morris says, "During extension they resist rotation outwards of the tibia upon a vertical axis," and a sprained knee is almost always caused by a twist outwards of the foot.

3. For the shoulder at the point corresponding to the bicipital groove, because in nine cases out of ten a man sprains his shoulder to prevent himself from falling, his hand grasps the nearest support, the body is violently abducted from the arm, the long head of the biceps is called upon to exert its utmost restraining power, the bicipital fascia is overstretched, and the tendon very often displaced.

Again, for the elbow the painful place is at the front of the tip of the internal condyle; the fan-shaped internal lateral ligament has its apex at that point, and it is most stretched in over-supination, with extreme extension of the forearm. On the front of the external malleolus, at the apex of the plantar arch, the tip of the fifth metatarsal bone, the styloid process of the ulna, the inside of the thumb, and the annular ligament in the front of the wrist, are respectively the most painful spots when those joints are severely sprained.

The manipulative part of the treatment of joints stiff from being sprained may be briefly said to consist in pressure over the part most injured, and momentary extension of the limb, followed by sudden forcible flexion. The method of doing it varies with each joint, and I can with confidence refer you to the descriptions given by Dr. Wharton Hood, as being faithful word-pictures, supplemented, too, by very accurate drawings.

The following are some of the lesser injuries the non-recognition of which has frequently come under my notice at Whitworth. In the upper limb: Fracture of the tip of the acromion; partial luxation of the acromio-clavicular and sterno-clavicular joints (often happening to men who carry weights on their shoulders); partial dislocation of the long head of the biceps, with over-extension of the bicipital fascia (common in men who throw weights or use a shovel, as malsters or navvies). Dislocation of the head of the radius forward on the condyle, which is very common in children, and has a marked tendency to cause stiff elbows; fracture of the tip of the internal condyle; overlooked Colles' fracture; partial luxation of the head of the ulna (impeding supination of the hand, and having a tendency to gradually grow worse); severe sprain at the carpo-metacarpal joint of the thumb (very common in stonemasons, and caused by the "jar" of heavy chisels).

In the lower limb: Fracture of the fibula just above the malleolus and at its tip (these are fruitful sources of lameness, often overlooked, and, if of old standing, very troublesome to treat); partial rupture of the ligamentum patellæ at its insertion into the tubercle of the tibia, which is much more common than is ordinarily supposed;<sup>3</sup> neglected over-stretching of the ligaments of the plantar arch, and tearing of the plantar ligament at its insertion into the os calcis; rupture of the penniform muscular attachments of the tendo Achillis, and muscular hernia in the calf.

I trust I shall be forgiven if I have dwelt too much on the *docteurie* of some of us, but I am sure so-called trifling injuries deserve more attention at our hands, since living at the high pressure men do nowadays, with every part of their bodies taxed to its utmost capacity, the slightest impairment of the mechanism of a limb must be an incalculable source of personal annoyance, discomfort, or disability.

<sup>3</sup> I have seen almost complete rupture unrecognised; while tearing of the ligament from its extensive insertion into the surface of the tibia is very frequent.

THE MUSICAL SOCIETY OF UNIVERSITY COLLEGE, LONDON.—This Society, having secured the co-operation of Mr. Alberto Randegger, will hold its first practice meeting in the Mathematical Theatre on Friday, November 24th, at 4.30 P.M.

## CONGENITAL CYSTIC HYGROMA.<sup>1</sup>

By EDMUND OWEN, F.R.C.S.,

SURGEON TO ST. MARY'S HOSPITAL.

IN the volume of the Transactions of the Medical and Chirurgical Society for the year 1839 is a paper by Mr. Cæsar Hawkins upon the subject of the present communication. It is, so far as I know, the first treatise that we have upon these cystic growths, and I very much doubt if any matter of importance, either as regards their pathology, diagnosis, or treatment, was left by Mr. Hawkins for future writers to fill in.

Congenital cystic hygroma is by no means of unfrequent occurrence, and it is strange that so little notice is taken of it in our works on general surgery.

The first case to which I will direct attention is that of the little girl that has just been examined by the meeting. She is now between three and four years old. A few days after birth her mother noticed a swelling under the right side of the tongue, which, on being shown to the doctor who attended her, was called a "ranula." He refused, however, to interfere with it. The supposed ranula grew, extending across the floor of the mouth and amongst the muscles behind the symphysis of the maxilla, until a definite tumour appeared against the angle of the jaw. The little patient was then brought to me, when I told the mother that nothing was to be done to the tumour, which, as it was growing rapidly, might entail serious consequences. My impression is that this enormous mass has now ceased to grow. It is certainly harder than it was, though its cystic nature is still quite evident. It is not tender, nor does it apparently interfere with the child's health or with the nutrition of the skin. I am still content to watch and wait.

The second case is that of a boy of five months who was under my care at the Children's Hospital. He had a cystic hygroma of the size of a walnut in each subclavian region and in each axilla; it was doubtful whether the upper and lower tumours were in communication. Mr. Thomas Smith saw the child with me, and we agreed that no active treatment should be undertaken. When I next saw the little patient, after an interval of three weeks (the mother lived at a distance, and was not led to expect much from treatment), the upper pairs of tumours had almost met across the episternal region; there was difficulty on swallowing, and commencing oedema of the eyelids and of each upper extremity. Translucency showed the cystic nature of the superficial part of the subclavian masses. A week afterwards the mother came to tell me that the child had died on the previous day, and that the tumours had gone on growing so that at last the child could hardly breathe. She said also that the oedema of the hands and arms had gone on increasing until the day before the death, and that the legs and thighs had towards the last days also begun to swell. Her opinion was that death was caused by suffocation. No post-mortem examination was made.

Here, then, are reports of two cases of, so far as one can tell, a similar pathological nature, in one of which fatal complications brought on a sudden termination, whilst in the other a quiescence which one hopes is genuine seems to point to the fact that activity of growth has given place to spontaneous degeneration or atrophy. It is impossible to say what course a cystic hygroma may take; whether it is about to undergo immediate or future growth, or whether it is about to undergo interstitial changes which shall reduce it to a "loose pendulous bag of fat." Inflammation of the tissues, either spontaneous or induced, will at times determine their atrophy, and from the increasing hardness in the case of the little girl, I suspect that such a change is at hand. As Mr. Hawkins remarked, some of these tumours look as if they could be easily dissected out, but to remove one from the neck the operator may have to work around the carotid vessels and possibly behind the pharynx. I once dissected such a tumour from the side of the chest, and even then I had to root it out from beneath the border of the latissimus dorsi. Mr. Hawkins suggested that their treatment should consist in puncture of the larger cysts, and in the application of pressure and counter-irritants. To which

<sup>1</sup> Read before the Medical Society of London, Nov. 6th, 1892.

one might perhaps add that in certain cases atrophy may follow the inflammation caused by the presence of one or more setons through the mass. Probably spontaneous inflammation is their most desirable complication.

In conclusion, I would remark that, as in the first case, a congenital cystic hygroma in the sublingual region may be mistaken for a ranula, an error in diagnosis which is more likely to lead to disappointment than to damage. That in whatever situation it may occur it is apt to be mistaken for a subcutaneous nœvus, or for one beneath the mucous membrane; and, lastly, that at times the resemblance to a fatty tumour is extremely close.

A second child exhibited possesses the remains of a hygroma on the arm. The patient has been three years under observation, but the mass, which now resembles a diffuse fatty tumour, was, when first under observation, of evident cystic formation. This is the only instance which I have seen of a congenital cystic hygroma situated upon an extremity; their favourite seat is the armpit and the floor of the mouth.

Seymour-street, W.

## PENETRATING WOUND OF THE ORBIT, INVOLVING THE BRAIN;

NO MARKED SYMPTOMS UNTIL THE THIRD DAY.

By ENGLEDDUE PRIDEAUX, L.R.C.P., M.R.C.S., &c.

W. T—, aged twelve, was playing with two other boys on the morning of Feb. 24th. The boys had hazel sticks about two feet long and half an inch in diameter, pointed at one end and cleft at the other, and in the cleft they fixed stones. One boy in slinging his stone let the stick slip, which went off with the stone and struck the patient in the right eye, entering by the pointed end. The boy pulled the stick out and walked home, about a mile, and told his father he had been struck in the eye. His mother bathed the eye, which appeared uninjured, and thought no more about it. They remarked that blood came from his nose and mouth. However, the boy remained well until the following Saturday. When he got up that morning his eyelids were so swollen he could not open them; he complained a good deal of pain. His eye was poulticed, but he was not kept in bed. He took his meals; and beyond complaining of the pain was not otherwise affected. In the evening, after he had taken his tea and gone to bed, he was found insensible, and I was sent for. When I arrived the boy was quite unconscious and very restless, turning over and over. Pulse 120, regular; temperature 101°. The eyelids were so much swollen I could not open them. A little pus was oozing out at the inner angle of the eye and some coming down the nostrils. He was quite unable to swallow. I placed a little calomel upon his tongue. The next morning he was quieter, his attention could be arrested by shouting to him. I got him to swallow a few spoonfuls of milk. Pulse and temperature the same. He died the same night, becoming more and more comatose during the day.

I made a post-mortem examination, and found a small external penetrating wound at the inner angle of the eye, but all the structures of the eyeball were quite uninjured. Internally I found a small ragged hole, large enough to admit the little finger, at the junction of the sphenoid and ethmoid bones. The under surface of the anterior lobe of the right cerebrum was completely destroyed. On placing the brain in water it all washed away, leaving a large ragged cavity the size of a duck's egg, and in which were two pieces of bone each as large as a threepenny piece. The whole brain was highly congested, with a patch of fresh lymph as large as a shilling under the dura mater at the vertex.

Wallington, Somerset.

PRESENTATION.—On the 9th inst. Dr. Scott Orr, on behalf of the nurses of the Glasgow Royal Infirmary, presented Dr. Thomas, for fifteen years superintendent of the infirmary with a large and handsome silver tray, bearing a suitable inscription. The testimonial was given as a token of the regard of the donors for Dr. Thomas, and as an evidence of their high sense of the efficient manner in which his various duties had been performed, and of the kindness which he had invariably shown to them.

A Mirror

## HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alla pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. IV. Proœmium.

### MIDDLESEX HOSPITAL.

#### TWO CASES OF FRACTURE OF THE SKULL IN YOUNG PATIENTS.

(Under the care of Mr. GEO. LAWSON.)

THE two following cases show from what severe injuries of the head young patients may recover. In the first case there was an indented fracture of the skull; and although there was a considerable depression of bone, yet, with the exception of a slight drowsiness for a few hours after the accident, the child had no cerebral symptoms, and left the hospital after three weeks quite well; indeed, he was only detained in the hospital because it was probable that some head symptoms might arise. The second case is very remarkable. The child fell the height of seventeen feet from a loft on to the stones below. There was without doubt a fracture of the vertex extending into the base of the skull, as was evidenced by the repeated vomiting of blood, the altered shape of the skull, and the intense and prolonged coma. The child was admitted on September 30th in a state of deep coma, and she remained in a state of unconsciousness five days, until October 5th, and unable to swallow any food except three teaspoonfuls of milk on the afternoon of the 4th. During this period she was fed with nutrient enemata. To account for this prolonged insensibility there must have been severe brain lesion, and yet the child has recovered, and now, without any apparent discomfort, is able to play with her toys, and behave as if she suffered no inconvenience from the injury. Another interesting point in the case is the time which elapsed before she was able to speak. It was not until the sixteenth day after the accident that she could be induced to answer any question, although, apparently, she often tried to say something.

CASE 1. *An Indented Fracture of Skull; very Slight Head Symptoms; Recovery.*—John G—, aged sixteen months, was admitted into Bird ward on July 8th, 1882, with an indented fracture of the skull. Shortly before being brought to the hospital the child fell off a high stool, and in his fall his head came into direct contact with the abrupt end of the leg of another stool which had been overturned.

*State on admission.*—There was a depression in the skull just above and to the left of the occipital protuberance, which corresponded exactly to the end of the stool. The depression was about one-tenth of an inch deep, visible to the eye, and the sharp edge of the surrounding bone could be easily felt with the finger through the integument. The child seemed drowsy, but, with this exception, there were no cerebral symptoms. The anterior fontanelle was not completely closed, but the posterior fontanelle was quite filled in with bone. An ice-bag was applied to the head, and the child kept quiet in bed.—9th: The child seems very well, and in no way affected by the accident. He soon recovered from the drowsiness, and eats and sleeps well, and plays well.—20th: The child has been kept in the hospital lest head symptoms might arise. He is very well and cheerful. The indentation, so marked on admission, is much less, the depressed bone having been partially raised towards the surface.—31st: As the child seems quite well he was discharged from the hospital. There was still a slight depression of the bone.

CASE 2. Ethel D—, aged six, was admitted into Bird ward on Saturday afternoon, September 30th, 1882, having just fallen from a stable loft on to the stone paving below, a height of seventeen feet. She was standing on a chair playing, when she tipped forwards and fell head foremost on to the paving, her head first striking the ground.

*State on admission.*—The child was in a state of profound coma. The left side of the head was very large from an extensive hæmorrhage beneath the scalp. Soon after her admission she vomited a quantity of blood, and twice the next day threw

up blood, but in less quantity. She was unable to swallow, and a teaspoonful of milk put into the mouth ran out again. Ordered an ice-bag to the head, and to have an enema of beef-tea and an egg, an ounce and a half every four hours.—Oct. 1st: The child still lies in a state of coma. Has vomited once some blood. Neither moves nor speaks. To continue the enema, as she is unable to swallow.—2nd: The child remains in the same unconscious state, but she shifts her position and draws up her legs, and is at times restless. She is unable to swallow. To continue the enema.—3rd: Still unconscious and unable to swallow; and although repeated attempts are made to give the child a teaspoonful of milk, it always runs out of the mouth. As she is very restless, and with difficulty kept in bed, a wooden frame has been placed around the bed, to keep her from falling out. To continue the enema.—4th: To-day the child seems to be better. She is still very restless. During the afternoon she swallowed about three teaspoonfuls of milk. As the bowels have acted twice the enema is given at longer intervals.—5th: The improvement has continued. She has taken half a teacupful of milk by the mouth, and is gradually regaining consciousness, and will look up when spoken to. The swelling of the side of the head is much diminished, but still there is fluctuation beneath the scalp on the left side of the head. To continue enema.—6th: The child is much better; she sits up in bed, and takes food. Ordered chicken, and milk with bread-and-butter. Omit enema. She has not yet spoken, although she clearly understands what is said to her. From this time the improvement continued. She began to play with her toys, and to take an interest in things around her. She would frequently try to speak, but was apparently unable to do so. The first time she spoke was on October 15th, when she answered "Yes" to a question put to her by the nurse. For the next two or three days she could only be induced to say "Yes" or "No."—24th: The child is now rapidly approaching convalescence. She talks freely, and plays all day on the bed with her toys. The blood beneath the scalp has been absorbed, and the left side of the head (the part on which she fell) is considerably flattened, but it is gradually regaining its natural shape. She has never complained of any pain in the head. There have been no paralytic symptoms either of the extremities or any of the parts supplied by the cranial nerves. The child will be kept for some weeks under observation in the hospital.

### NORTHAMPTON GENERAL INFIRMARY.

A CASE OF ACUTE CHOREA COMPLICATED BY PERICARDITIS, ENDOCARDITIS, CELLULITIS, ETC.

(Under the care of Dr. FRANK BUSZARD.)

FOR the following interesting notes we are indebted to Mr. J. Oswald Lane, assistant house-surgeon.

J. D—, aged fifteen, was admitted on June 19th into the hospital with the following history:—He is one of a family of eight children, all of whom are rather delicate, but the patient himself has never been laid up before the present illness; has never had rheumatism; no history of shock or of overwork of mind or body; has always been a sharp lad, and no members of the family have been affected with nervous disease. The first appearance of the present illness showed itself on June 6th, when he was seized during the night with excruciating pain in the right leg, followed the next morning with "snatching" of the muscles of the right half of the body, though both sides of the face were affected. These movements became gradually more marked and general. Two days before admission he first began to wander, while at times insensible; at others very noisy; cracking of skin also noticed.

On admission the choreic movements were general and of the most marked form, especially so of the face and arms. He was very noisy, crying out furiously; at times sensible, but unable to answer in articulate sounds. Skin very dry and cracked, lips fissured, tongue brown, covered with sordes. There were distinct signs of hyperæsthesia; pupils dilated and sluggish to the action of light. Pulse 120; temperature could not be taken.

June 20th.—Passed a very noisy and restless night, delirious at times though occasionally sensible; spasmodic movement of the muscles still just as marked, and is unable to articulate words or swallow.—21st: Much quieter, whilst the

choreic movements have almost stopped; power of articulation and swallowing just the same, while the respiration is very jerky; there is a distinct pericardial murmur with no increase of dulness. Pulse 124. Urine shows an increase of urea.—23rd: Movements still present; can now swallow liquids; sometimes utters articulate sounds and nods when asked questions. Area of cardiac dulness increased, friction; bronchitic sounds; signs of inflammation in left forearm; also of right wrist and hand. Pulse 130; respiration 35. Temperature, morning 99° 6'; evening 98° 6'.—25th: Choreic movements abated. Can now say some few words, such as "Mother," "Nurse," "Yes," "No." Sordes less; bronchitic sounds to be heard, while the cheeks are flushed. Incision was made into the left forearm, when a large amount of pus was evacuated. Skin still cracked. Pulse 128; respiration 38. Temperature, morning 99°; evening 100°.—26th: Pulse 133; respiration 32. Temperature, morning 100°; evening 100° 2'. Cellulitis still increasing, as also the area of cardiac dulness.—27th: Temperature, morning 100°; evening 100° 2'.—28th: Temperature, morning 100°; evening 100° 4'.—29th: Temperature, morning 98° 8'; evening 102°. A large amount of purulent discharge from the incision made into the left forearm; right hand swollen, but no feeling of fluctuation. Tongue cleaner; appears better though still extremely prostrate; choreic movements have entirely disappeared; he is able to speak more distinctly, but only a few monosyllables. Bowels confined; appetite improved. Respiration 30, at times irregular and laboured. Pulse 132.—30th: Temperature, morning 99°; evening 102° 2'. Discharge copious.

July 1st.—Temperature, morning 102°; evening 101° 8'.—3rd: Temperature, morning 100°; evening 102° 4'. An incision was made into the palm of the right hand, when a large amount of curdy sanguineous pus exuded. Abdomen tympanitic; heart's area of dulness has gradually increased, no endocardial murmur to be heard; appetite improved. Pulse 126, not wiry; respiration 32.—4th: Temperature, morning 99° 6'; evening 103° 8'; discharge copious.—8th: Temperature, morning 100°; evening 103° 2'. Discharge from right hand, though copious, has diminished in quantity; some swelling of the right arm below elbow; no joints affected; area of cardiac dulness has increased downwards, and towards the axillary line no exocardial murmur, but a distinct soft systolic murmur can be heard at the apex; tongue fairly clean; takes nourishment well; some flatulency. Pulse 128; respiration 32.—9th: During last night he perspired copiously and does not seem so well this morning; this was accounted for by a collection of deep-seated pus in the right forearm, which was evacuated by incision. Temperature, morning 101° 2'; evening 102° 2'.—13th: The patient has improved the last few days; his temperature has gradually defervesced; his speech is much improved, as he now talks correctly but slowly; expression brighter and tongue clean. Temperature, morning 99°; evening 99° 2'.—19th: The last two days his febrile symptoms have become marked, while he complains of tenderness in right palm of hand, and some slight pain in right thigh. Temperature, morning 98° 8'; evening 102° 2'.—20th: Another incision was made into the right hand, giving a free exit for purulent matter; during the next few days the febrile symptoms greatly diminished, and he improved rapidly in general health.—30th: From the time of the last notes the patient has gone on gradually improving, his temperature has been normal for several days, and all the discharge has stopped. He is now allowed out of bed; the systolic murmur has become much more marked, and can be heard over a larger area than previously. He was discharged on August 6th convalescent, the systolic mitral murmur alone remaining.

*Medicinal treatment.*—During the first ten days after admission small doses of chloral and digitalis were administered, followed then by the liquor cinchonæ (Battley's) in five-minim doses every four hours. He was kept on the latter treatment for one week, when sulphate of magnesia in twenty-grain doses every four hours was administered. This was continued for three weeks, when iron and quinine were given him till his discharge.

*Remarks.*—This case here recorded has several features of interest in connexion, amongst which may be enumerated:—1. Marked choreic movements developed themselves previous to any apparent signs of pre-existing pericardial mischief, inasmuch as the physical signs which manifested themselves on the third day after admission were those of commencing pericarditis, as the subsequent history of the case will show. 2. Pericarditis followed

by endocarditis presented itself without any assignable cause; there was an entire absence of any rheumatic history in *propria persona* or hereditary. 3. The severe phlegmonoid inflammation of the cellular tissue which developed itself; this probably being of a pyæmic nature, dependent upon the existing cardiac complication. 4. The acuteness of the attack in the male sex, with subsequent recovery.

### ESSEX AND COLCHESTER HOSPITAL.

UNUNITED FRACTURE OF OLECRANON; ENDS UNITED BY OPERATION; CURE.

(Under the care of Mr. LAVER.)

CHARLES C—, aged thirty, a mariner, was admitted on Oct. 27th, 1881, for ununited fracture of the olecranon. On examination the two portions of bone were found to be sufficiently apart to allow two fingers to be placed between them. This separation caused loss of power, and there was also some tenderness on pressure. The accident (a fall on the deck at sea) by which the fracture was produced occurred on August 13th, 1881. His arm was properly placed on a splint, but with the result above mentioned, and it was determined to try to unite the fragments, and for this purpose on November 4th an operation was performed under full antiseptic precautions. The bones were exposed, scraped, drilled, and wired together with stout silver wire, the joint syringed out with carbolic water, and the arm placed on a front splint. On the 6th the limb was dressed; there was a slight stain of discharge, but no inflammation. On the 11th it was dressed again, and the stitches were removed. On the 20th it was dressed, and then there was no discharge. When dressed on the 25th there was no discharge, and the wound was healed.

On December 22nd, the wire in being removed snapped off and could not be taken out. The patient could move his arm freely without pain, and union had taken place, and he was discharged on leave of absence.

Jan. 2nd, 1882. — Patient returned, complaining of a pricking sensation; it was found to be caused by the broken wire, which was cut down upon and removed.

Feb. 6th. — Long extension splint, which had been on his arm, removed. On the 20th he was discharged cured, with perfect union and full power.

Remarks. — The case was kept a long time on the splint in consequence of the man's occupation, and the unfortunate accident of the wire breaking in further lengthened it.

## Medical Societies.

### ROYAL MEDICAL & CHIRURGICAL SOCIETY.

*The Endemic Hæmaturia of the South-east Coast of Africa. — The Life History of the Liver Fluke.*

THE ordinary meeting of this Society was held on the 14th inst., J. Marshall, Esq., F.R.S., President, in the chair. There was an unusually large attendance of Fellows and visitors. The evening was devoted to the interesting subject of parasitic diseases, especially the Bilharzia and Fasciola hepatica. A paper on the former subject, written by the late Dr. Lyle of Durban, was communicated by Dr. J. Harley; and Drs. Cobbold and Crocker exhibited specimens of the parasite and allied forms. Mr. Thomas related his admirable research into the life history of the liver fluke. He deserves the credit of having conclusively determined the species of mollusc that acts as intermediary host of this parasite, so destructive to our flocks. He exhibited numerous specimens, and his relation of the developmental changes of the fluke was illustrated by diagrams. Other specimens of parasites were exhibited by Professor Ray Lankester, Dr. Bastian, and Dr. S. Mackenzie.

The following is an abstract of the paper on the Endemic Hæmaturia of the South-east Coast of Africa, by the late Dr. VASY LYLE, of Durban. (Communicated by Dr. JOHN HARLEY.) The author, in the first place, discusses the physical characters of the infested country, and the extent of the country infested. He states, as an almost completely

proven fact, that the Bilharzia infests the whole eastern littoral of Africa, from Egypt to the Cape; and that the entozoon found amongst the people of the Nile valley is identical with that found in South Africa. It appears to inhabit the sluggish parts of rivers and low marshy lands, and to be absent from high lands; the interior plateau of South Africa being free from the disease. The present immunity of Port Elizabeth is attributed to the substitution of rain water stored in tanks for that of wells and pits. Opportunities were obtained of examining the bladder in a case of the disease, and both the male and female parasite. The bladder in one case was healthy near the neck, but crossed thence diagonally to the fundus by fungous-looking growths, and the mucous membrane over these was granular and ulcerated, and contained embedded ova. One female Bilharzia was dissected out. The author agrees generally with the description given of the parasite, but differs in some minor points. In reference to the symptoms and progress of the disease, the author remarks that no symptoms of the affection have been observed antecedent to the appearance of the hæmaturia, the general course of the disease being that described by Dr. Harley in his communications to the Royal Medical and Chirurgical Society. Illustrative cases are given, and one of them contains the evidence of a Kaffir on the prevalence of the disease amongst the natives. — Dr. COBBOLD had brought to the Society specimens of urine from five out of seven cases that had been lately under his care. One of these, which a year ago was loaded with blood, was now quite clear, but still contained ova, and the ciliated embryos hatched from them were shown under the microscope. He also exhibited specimens of the adult Bilharzia sent him by Professor Leuckart and Sir J. Fayer, as well as specimens of the parasite from oxen and sheep, differing from the human varieties in the spindle shape of the ova. After referring to the discovery of the parasite by Bilharz in 1851, and his own discovery of it in a monkey in 1857, the speaker said that its clinical bearings and geographical distribution were dealt with by Dr. J. Harley in his paper read before the Society in 1864. The parasite had since been found in India as well as in Natal. Although from analogy it was thought to have its intermediate host in molluscs, the variety of mollusc had not been found—probably not a British form. He described the three modes of dealing with the disease as the "heroic," the "do-nothing," and the "rational" plans of treatment. Of the first Dr. Allen had lately given an example, advocating injection into the bladder of saturated alcoholic solution of eantonin. This produced severe cystitis, and the fact quoted in support of its efficacy, that the patients did not return for further treatment, was capable of an opposite inference to that given by Dr. Allen. The second plan was based on the idea that patients will out-grow the affection. But Dr. Cobbold had under his care in 1870 a girl who was passing an enormous quantity of the ova, and is now strong and well. The treatment then adopted was tonic and nutritious, which succeeded, he believed, in saving her life. He therefore recommended treatment to support the system—quinine and iron, ample food, &c. Buchu was useful, and in bad cases it might be well to try such parasitocides as perchloride of mercury, given internally. — Dr. CROCKER referred briefly to the case from which the embryos and ova of Bilharzia that he exhibited were taken. In that case the hæmaturia, which had been profuse, was now almost absent; but ova were still being found. The nature of the disease was detected by examining the clot microscopically. — Dr. J. HARLEY believed that the parasite gained ingress into the bladder through the urethra while bathing. It is not common in females, but almost every lad in infested districts suffers from it, and it was a practice with the natives to tie a tape round the penis to prevent its entrance. Although in Cairo the disease seemed to be taken by drinking water, in Natal, the view he held seemed more likely, especially as the parasite was located in the pelvic organs. He had early advocated treatment by injections into the bladder, and had used iodide of potassium and oil of male fern for this purpose. Dr. Harley referred to a case so treated with success. As to the apparent disappearance of the disease, mentioned by Dr. Vasy Lyle, Dr. Harley cited an instance of two young men from Port Elizabeth, who were said to have had the disease in boyhood and were supposed to be free from it when seen by him (Dr. Harley). But he found ova in the urine of each, and had later to attend them for attacks of renal colic and oxalic calculi. Dr. Harley concluded by referring to the author of the paper, who was a type of the

honest scientific worker, and who seems to have been the only medical man in South Africa who had devoted such labour and patience to the investigation of this disease.

At the invitation of the President, Mr. A. P. THOMAS, M.A. (of Oxford), then described his researches into the Life History of the Liver Fluke, researches which had been undertaken at the request of the late Professor Rolleston on behalf of the Royal Agricultural Society. After mentioning the ravages made by the liver fluke (as many as 3,000,000 sheep being lost by it in this country in the year 1879-80) and referring to the fact that hitherto the search after the particular mollusc supposed to harbour its larval form had been futile, Mr. Thomas described his plan of work. He thoroughly searched meadows for every species of mollusc likely to be an intermediary host, dissecting them without success, until at length he succeeded in finding in the small *Limnæus trunculatus*, a cylindrical worm or *Reedia* containing cercaria. The cercaria is of tadpole shape, and has the peculiar habit of encysting itself directly it is brought into contact with any solid object, the material for encystation being exuded from some lateral masses in the body of the larva. For some time the inquiry was arrested because of his inability to find any more specimens of the *Limnæus trunculatus*, even where they had abounded in the previous year. In last July, after floods, however, he found an ample supply in the flooded meadows. The snail in question is more truly amphibious than a water snail, is very small—about a quarter of an inch long—and wandering along the damp roots of grass, its presence may readily be overlooked. He now proceeded with infection experiments, and succeeded in proving that this mollusc was the sole intermediary host of the common fluke. At the same time he was enabled to study fully the metamorphosis of the latter. The liver fluke is very prolific, but so long as the ova remain in the liver they undergo no further change. In artificially hatching them, the embryo is seen to leave the egg by the sudden giving way of the operculum; and once in water the cilia with which the body of the embryo is covered came into action. The free swimming embryo has a spindle shape and is provided with a double eye spot (two masses of pigment), and is very sensitive to light. If the embryo comes in contact with a *Limnæus trunculatus* it begins to bore into its shell, the head papilla becomes elongated and sharp, and by a sudden movement the boring is effected, and the body of the embryo passes into the snail. As soon as it gets into the snail the body contracts, its outer layer is cast off, and it degenerates into a sporocyst. By proliferation of cells lining the body cavity and of cells in the body walls, masses of germinal cells are formed from which the cercaria is developed. The sporocyst usually develops in the pulmonary cavities of the snail and the parasite gets into the liver, feeding on the liver cells. The cercaria is formed by the rounded germ-masses becoming elongated, one end being pinched off to form a tail. When the cercaria has escaped and become encysted, it remains quiescent until swallowed by the sheep; when the cyst being dissolved the embryo fluke finds its way into the liver ducts of the sheep. Mr. Thomas concluded his statement by pointing out that the real preventive of the disease is salt, a small quantity of which will not only kill the larvæ of the fluke, but the *Limnæus* also. The salt should be scattered over all land where the snail is believed to be present. It had also been found useful to feed sheep on salt, and this had been long a practice among farmers who had found it valuable in preventing sheep rot, but who had not thoroughly carried it out. Many other animals, including man, were liable to be infested by flukes, and in the case of man the parasite might be introduced through watercress.—Dr. COBBOLD said that he exhibited specimens of flukes from the elephant, giraffe, &c., and that even whales, porpoises, and dolphins were liable to such parasites. He thanked Mr. Thomas for having conclusively proved the *Limnæus trunculatus* to be the intermediary host of the common fluke; and remarked that, curiously, a year ago he had believed that Leuckart had made the same discovery. But he had since heard that Leuckart thought it was another species of *Limnæus*, so that Mr. Thomas had succeeded in a search which the great German helminthologist had been so long pursuing.—Dr. J. HARLEY mentioned the case of a labourer who died from this disease, twenty-six flukes being found in the hepatic ducts, and the symptoms being most obscure. It was ascertained that his diet had consisted chiefly of bread and cheese, often accompanied by watercress.—Dr. MACLAGAN mentioned that a gentleman in Dor-

setshire had told him that in 1879-80 he had lost none of his sheep from this disease, whilst all round there was great mortality. His immunity was attributed to his flocks being fed with salt.—The PRESIDENT thanked Mr. Thomas for his lucid exposition, and pointed out the great importance of the study of diseases of animals as throwing light on those of man, and of the importance of prevention in such diseases. It was a reproach that our troops should be exposed to such disorders, when the means of prevention were not far to seek.

## CLINICAL SOCIETY OF LONDON.

### *Hysterectomy.—Spina Bifida.—Diastasis of Clavicle.—Local Treatment of Diphtheria.*

THE ordinary meeting of this Society was held on Friday, Nov. 10th, Mr. J. Lister, President, in the chair. For the first time, in accordance with the new regulations, card specimens were shown. The President announced that he had heard from Prof. Pantaleone of Rome, expressing his gratification at the honorary membership of the Society recently conferred upon him. Mr. Clutton's cases of spina bifida excited a good deal of discussion, at the close of which the President nominated Messrs. Clutton, Pearce Gould, Howard Marsh, and Parker as a committee to inquire into and report to the Society upon the results of Dr. Morton's treatment of this deformity.

Mr. GOLDING BIRD narrated a case of Removal of a Fibroid Tumour, with Extirpation of the Uterus, that had ended fatally. The patient was thirty-seven years of age, and had had the tumour for three years. Its increasing size, the pain and weight accompanying it, and the repeated and prolonged attacks of nausea occasioned by it, compelled her to seek surgical relief. The tumour—the size of the uterus at six months—grew from the anterior wall of the cervix, and lay between this and the bladder, with the latter of which it was intimately connected. The uterus itself was all but drawn out of the pelvis, and the two ovaries, both cystic, could be felt through the abdominal parietes, and prior to the operation were thought to be bosses on the tumour. The operation was fully described, and special mention was made of the use of an apron of green carbolised protective well tucked in over the intestines when the abdomen was opened, whereby they were easily kept out of the way and sheltered from the spray. The tumour had its peritoneal investment circumferentially divided where it was reflected on to the pelvic walls or viscera, and it was then shelled out from its bed, the broad ligaments being previously divided. The union with the uterus was intimate, and had to be severed, while the connexion of the fibres of the tumour with those of the bladder rendered the operation very difficult. All bleeding was stopped with carbolised silk ligatures, and the peritoneum, where divided between the rectum and bladder, was united with a continuous suture at the completion of the operation. The uterus and ovaries were removed after the tumour, a pedicle being formed out of the cervix uteri; it was tied in four parts, as in Erichsen's method of tying *nœvi*. Before the closure of the peritoneum a rent in the bladder had to be carefully sewn up; a catheter was tied in. The general conduct of the case was like that of ovariectomy. For forty-eight hours all went well, and then severe vomiting set in, which eventually exhausted the patient, and caused her death on the fourth day. The post-mortem showed repair to have been perfect as far as it had gone; there was no evidence of the urine having passed beyond the limits of the bladder. There was no suppuration, and only slight pelvic peritonitis. There did not seem to be enough to account for the vomiting, and the author explained this symptom as depending upon some idiosyncrasy of the patient, inasmuch as when she had typhoid fever ten years before, vomiting severe enough to threaten life was then the most prominent symptom. The specimens removed at the operation and the parts reserved at the post-mortem were exhibited.—Mr. KNOWSLEY THORNTON would like to ask Mr. Golding Bird as to two points in the case which his record seemed to omit: What was the pulse rate? He did not attach much importance to temperature alone in these cases, but had frequently seen patients die of incessant vomiting without any marked high temperature, but with a constantly ascending pulse. He believed such deaths were from septic absorption. In

this case everything was specially favourable for such a result, in spite of the use of Listerian details, because the uterine stump, which always contains causes of putrefaction, was ligatured and then enclosed with a mass of other wounded and ligatured tissues in a space between the closed peritoneal flaps and the tissues forming the floor of the pelvis, with no possible outlet for effused materials except through the cervical canal, which was closed by the constricting ligatures. Supposing the fluids in this space putrefied, as was most likely to be the case, their only outlet was through the sutured flaps into the peritoneum, and, doubtless, this was the origin of the eight ounces of red serum found there after death. The wounded bladder, with catheter tied in, would also be a very likely centre for sepsis spreading into the peritoneum. The absence of anything to account for death, when the post-mortem is made, is a special feature in these cases of septicæmia. The very peritoneal absorption which causes death itself removes the evidences. The second point he would ask for information upon was, What was the sufficient reason for such a serious operation? Mr. Bird had stated that the patient was in fair health, and that menstruation was not excessive. The fibroid was evidently quite a small one. What was the justification for this fearful operation? The authorities had long laid it down as a rule that hysterectomy for fibroids was only justifiable when life was in danger, either from hæmorrhage, excessive growth of the tumour, or some other cause. The mere wish of the patient ought not to be considered in these cases. He had himself on some previous occasions expressed sanguine views as to the future of hysterectomy, but recent observations and experience had led him to modify these views somewhat, especially as it was becoming the fashion to remove the uterus for fibroid disease in cases in which there were no urgent symptoms. The results of the operation recently in this country by the wire *serre-nœud*, and in Germany by the elastic ligature, were very encouraging, but the operation was still a very dangerous and formidable one, and ought only to be undertaken in grave cases. From what Mr. Bird had said as to the condition and position of the ovaries in this case, it seemed to have been a specially suitable one for removal of the uterine appendages, and this has been proved to be a much safer and a more successful process. Mr. Lawson Tait had pointed out a fact which he himself could corroborate—viz., that the ovaries are very commonly cystic along with fibroids of the uterus. Mr. Tait thought that the cystic ovaries cause the fibroids, but they are too often absent for this to be true. Mr. Thornton was long very sceptical as to the cure of fibroids by the removal of the uterine appendages, but he had now convinced himself that Mr. Tait was right in this matter. He had tried the operation in a small number of carefully selected cases, and had met with uniform success; all the patients had recovered; and all in the course of from five months to a year had lost their fibroids by gradual absorption. He did not attribute the result to the mere removal of the ovaries, but chiefly to the great alteration in the blood-supply, when all the enlarged vessels about the ovaries and tubes were tied. He had tested the operation in cases of subperitoneal fibroids, mural fibroids, and fibro-cystic disease, and in all the result had been equally good. With the statistics of this operation as to mortality, he did not think hysterectomy was justifiable without a previous trial of the safer operation of removal of the uterine appendages. At the same time it must be remembered that this operation was often a very difficult and dangerous one, and might end in the necessity for the performance of the still more dangerous hysterectomy from uncontrollable hæmorrhage. This accident happened to himself in two of his early cases. In reply to a question from the President, Mr. Thornton said that his cases of removal of the uterine appendages had not only all recovered, but had in course of time their uteri restored to their normal condition.—Mr. GOLDING BIRD replied that Mr. Bryant had advised him to proceed at once to removal of the entire organ rather than attempt incision of the uterine appendages at first. He had relied more upon the temperature than the pulse, especially as the patient was liable to great rapidity of the pulse from emotional causes.

Mr. CLUTTON related a case of Spina Bifida cured by Injection of Iodine. When three weeks old a child was brought to St. Thomas's Hospital, and was found to be a well-nourished, healthy child, with the exception of the above imperfection. The spina bifida was situated in the lumbar region, small, and with exceedingly thin walls. The impulse

when the child cried was very marked, and the aperture in the lower canal large. There was no paralysis of the lower limbs, and the cyst, examined by transmitted light, did not appear to contain the cauda equina. The skin had been so stretched that the walls were quite translucent, and would evidently have soon given way and allowed the fluid to escape. A week after it was first seen, and when the child was four weeks old, the cyst was injected with a drachm and a half of Morton's fluid, as little as possible of the contents of the sac being allowed to escape; a pad with collodion and bandage completed the treatment. The mother was instructed to keep the baby on its back, and prevent, as far as possible, the gravitation of the fluid into the vertebral canal. The constitutional disturbance was very slight, and on the third day the child was in its usual health. The cyst began immediately to shrink, and by the end of a week the skin was in loose folds. At the end of the third week there was nothing to be felt of the spina bifida, except a small puckered lump of cutaneous tissue. Mr. Clutton also mentioned a case of Occipital Meningocele, which he had treated by injection of iodo-glycerine without any effect, good or bad. And also another case of Lumbar Spina Bifida, with a very thin sac, in which the injection of about a drachm of the iodo-glycerine solution was immediately followed by the sudden death of the child.—Mr. MORRANT BAKER asked whether in the last case any fluid was withdrawn previous to the injection, and also what position the child was placed in. The record of such cases was very valuable as a guide to practice.—Mr. PEARCE GOULD asked Mr. Clutton whether in his first case the sac was covered with skin, and whether the fluid withdrawn contained sugar. The most favourable cases for injection were those in which the deformity consisted only of a hernia of the dura mater, the fluid being arachnoid fluid. As an instance of the fact that spontaneous cure occasionally occurred in the worst cases, he described a case of a very emaciated infant who was recently under his care with a large lumbar spina bifida which had burst, and a great part of the sac had sloughed; yet the tumour underwent a spontaneous cure, although the child died of marasmus.—Mr. A. E. BARKER had operated upon a case very much like the last one referred to by Mr. Clutton. The child was kept upon his back for some time after the injection. The operation had not the slightest effect upon the tumour, and he heard later on that the tumour burst and the child had died.—Mr. HOWARD MARSH mentioned the case of a child four months old. The tumour was not large, covered by fairly healthy skin, but was increasing. He injected the tumour with about one drachm of the iodine solution; the child became completely collapsed and died immediately after the operation. At the Children's Hospital the results on the whole have not been successful.—Mr. C. HEATH said that the injection of iodine into the cavities of the brain and spinal cord was not necessarily fatal. He had had under his care a case of anterior meningocele in a child six years old which had been previously injected with iodine by Sir James Paget without injurious effects. He thought that talipes calcaneus was very common in these cases.—Mr. R. PARKER had injected about twelve cases without meeting with any fatal result like Mr. Clutton, or other visible effect of the injection, but he had had only one successful case. The result depended upon the size of the spinal aperture, and whether the spinal cord were involved or not. In his successful case the sac was covered with healthy skin, and he injected less than half a drachm of the fluid every week for some weeks. He thought talipes calcaneus was not always present in some cases it was unilateral or equino-varus.—Mr. GODLEE added a case to the list of successful cases. The tumour was small, with a thin wall, and was cured by a single injection.—Mr. BENNETT had had only one case of this kind, and there the injection was unsuccessful. The sudden death after the injection of the tumour might be a mere coincidence in some cases, as was shown by a recent experience of his own. Not long ago he planned to inject a spina bifida on a certain day, but owing to the child being then unwell he postponed it, and the child died from convulsions while going home in the omnibus.—Mr. MORRANT BAKER mentioned a case in which the tumour was cured, but hydrocephalus increased, and gradual loss of power in the lower limbs came on.—Mr. CLUTTON said that in all his cases the child was kept lying on the back, and he injected slowly; he only withdrew a small quantity of fluid, and that gave a distinct reaction of sugar. In both cases

there were patches where there was no skin at all, and the sac was like tissue paper. In the first case there was no raw surface, in the latter the sac was partly ulcerated. The aperture of the sac into the theca vertebralis does not correspond with the size of the aperture in the bones.

Mr. CHRISTOPHER HEATH related a case of Separation of the Epiphysis of the Clavicle by Muscular Action. A boy, aged fourteen, whilst raising his arm violently to bowl at cricket felt something give way at his collar-bone. The inner end of the clavicle was found to be unduly prominent, and presented a sharp edge beneath the skin, quite unlike the smooth end of a bone, covered with articular cartilage. The supra-sternal notch was quite distinct and equally defined on both sides, and a thin lamella could be felt on the right side, intervening between it and the gap caused by the starting forward of the inner end of the clavicle. The treatment consisted in laying the patient down, when the bone at once slipped into its place, and it was retained by a plaster-of-Paris bandage. Mr. Heath referred to the great rarity of the accident, and the diagnosis of it from dislocation of the clavicle, and insisted upon the great utility of the plaster-of-Paris bandage in fractures of the clavicle and humerus.—Mr. LISTER said this case was exceedingly interesting and rare, if not unique. The diagnosis was no doubt correct, both from the sharpness of the projecting fragment and the presence of the lamella in the site of the injury.

Dr. GOODHART read a paper on Six Cases of Diphtheria treated by the local application of Borax or Boracic Acid. In four a saturated solution of boracic acid in glycerine was used, the application being made in part by a hand spray, in part by the laryngeal brush, and as often as every two hours in some cases. In the other two a diluted solution of the glycerine and boracic acid was used. The first case was a very severe one, and it died from renal complications on the seventh day; but the boracic acid and glycerine seemed to be so successful in relieving the throat symptoms, and in preventing the re-formation of the membrane, that it was determined to try it again. Of the other five three had croup as well as membrane on the fauces; one had nasal diphtheria; all had albuminuria. All recovered. Tracheotomy was necessary in one case, and the glycerine and boracic acid were freely applied to the interior of the trachea and larynx from the wound, and to the surface of the wound itself, and it seemed to be very beneficial in loosening, dissolving, and preventing the re-formation of membrane. In another case it is believed that tracheotomy would have been necessary had not the vigorous application led to the expulsion of membrane by the mouth. In all cases it seemed to give such relief that very little difficulty was experienced in carrying out the treatment. Both borax and boracic acid have been occasionally in use as a topical application in diphtheria, doubtless, for a long time past, but not, so far as is known, with any decided success; nor can it be supposed that any remedy will not often show a good proportion of failures in combating a disease such as this. It is enough to say that these agents are known to be good antiseptics, that their action is harmless when not beneficial, and that they are certainly useful in some cases.—Dr. PHILLIPS had carried out the treatment in the first of Dr. Goodhart's cases. He referred to two other cases similarly treated, in each of which tracheotomy was performed in a few hours, and every attempt to remove the membrane was made; but the children died, and in each case the membrane was found extending down into the smaller tubes. The strength of the solution is one part of glycerine to three of borax diluted with an equal part of water when used as a spray.—Dr. O'CONNOR had notes of nearly forty cases of diphtheria, but he had not met with much success in the use of a watery solution of boracic acid. He thought the best application on adults is a solution of chlorate of potash. He had often found that the membrane reappeared on its original site, thinner but evidently of the same nature as at first.—Dr. LONGHURST thought the treatment was good because it was non-irritating; much good was not to be looked for from local treatment of a disease which is essentially constitutional.—Mr. LISTER remarked that each physician extolled his own application for diphtheria. He had received striking reports of series of cases without any fatal issue treated locally by tincture of iodine. But its infective character clearly showed it was a local disease. Boracic acid is a wonderfully efficacious antiseptic, as is seen when it is applied to putrid onychia, for example.

It may very well act in this way on the membrane in diphtheria. Boracic acid, by the aid of heat, may be mixed in any proportions with glycerine.—Dr. GOODHART said that the constitutional nature of the disease was no argument against local treatment, as the disease is so often fatal from its local effects.

The following card specimens were shown:—1. A Case of Transpatellar Excision of the Knee, by Mr. Golding Bird. 2. A Man from whom the Tongue and part of the Lower Jaw were removed in 1876 for Epithelioma, no recurrence, by Mr. C. Heath. 3. A Case of Spontaneous Partial Dislocation of the Clavicle, in association with Lateral Curvature of the Spine from an unreduced Dislocation of the Hip, by Dr. Clippingdale. 4. A successful Case of MacEwen's Operation for Genu Valgum, by Mr. Keetley.

## MEDICAL SOCIETY OF LONDON.

### *Congenital Cystic Hygroma.—The Treatment of Wounds.*

At a meeting of this Society, held on the 6th instant, Mr. F. Mason, President, in the chair,

Mr. EDMUND OWEN exhibited two cases of Congenital Cystic Hygroma, and read a short paper on them (see p. 845).—The PRESIDENT was not satisfied that the tumour on the side of the cheek communicated with the cyst beneath the tongue.—Mr. BRYANT remarked that the cases were seen in a later stage, and no communication between the larger tumour and the mouth was to be found. He advised enucleation and removal. In its present state the smaller tumour might be taken for a congenital naevus. In three cases he had noticed hygroma to be associated with imbecility.—Mr. OWEN, in reply, admitted that perhaps there was no communication between the two cysts in the first case, but he thought they were connected by fibrous tissue. In the second case, he thought the hygroma was degenerated. The difficulties of removal of the cyst in the first case were very formidable.

Mr. SAMPSON GAMGEE then read a paper on the Treatment of Wounds (see p. 840).—The PRESIDENT asked if Mr. Gamgee made any difference in treatment between hospital and private cases.—Mr. W. ADAMS coincided entirely with the principles laid down by Mr. Gamgee. The exclusion of air and water were the leading features of his own practice. Wounds from which air and water were excluded ran the course of subcutaneous wounds. He presumed that Mr. Gamgee excluded water as favouring decomposition. What did Mr. Gamgee use when wounds required to be washed? The principle of firm support and even compression was unduly neglected in modern practice. Richardson's colloid styptic he used extensively in his own practice, and knew nothing of the kind so valuable.—Dr. RICHARDSON suggested that it deserved to be determined by surgeons what was the precise thermometric indication for taking off the dressing from a wound. What account, in respect to rise of temperature, ought to be made for natural reaction? What degree of temperature should be considered as necessary to determine interference with the dressing? What time of continued increased temperature should be allowed to elapse before such interference? There ought to be a fair approximative general rule on this subject. Referring to the practice inculcated in Mr. Gamgee's paper, he said that in principle it dated long back. It was a treatment more or less in use ever since Friar's balsam was known as a remedy for wounds. It contained the true secret of Sir Kenelm Digby's expectant non-interfering method; it was the method enforced in a past century by Belloste; it was a method which, in this country, has from the last century into the present held its own. It had sometimes been supplemented by extraneous and fanciful procedures. Sir Kenelm Digby and his adherents had supplemented it by introducing, as an adjunct, the sympathetic powder with which the sufferer was taught to polish the weapon which caused the wound, as if that were a part of the cure; and in our day we had seen it supplemented by procedures which in future times would read, he believed, as equally unnecessary and nonsensical. Mr. Gamgee had brought the practice back to its true physiological bearing by showing that the sustenance of life in the injured part itself was the cause of success in healing, apart from any mysterious local surroundings or imaginary destructive agencies. In cases where there is bleeding from a wound that has been inflicted some time, and

from which there is offensive odour, Dr. Richardson agreed with the author that the iodised was more effective than the styptic colloid. He agreed equally in opposing the employment of water for dressing wounds, and recommended for cleansing purposes proof spirit, containing tannin and glycerine, a solution which was at once a good wash and a good styptic. Dr. Richardson concluded by urging that the profession ought to continue on the splendid historic lines that had been laid down for it in the past, and that if, instead of pursuing this course, it allowed itself to be led away by the hypotheses of men, however distinguished, who did not belong to it, and did not understand its practical work, it would go down altogether in fact as well as in estimation.—Mr. PAGE did not think the thermometer a sufficient index of danger by reason of the various nervous temperaments of the different patients, which determined a rise in temperature in the reaction after a wound. Mr. Gamgee's paper was based on sound physiological principles; but he could not agree with Dr. Richardson's strictures on Listerism, which he thought would always be regarded as an effort to restore natural conditions to the seat of the wound.—Mr. E. OWEN corroborated Mr. Page's remarks about the varying degrees to which the temperature might normally rise in different persons.—Mr. BRYANT agreed with Mr. Page that Mr. Gamgee's paper was based on physiological principles. He noticed that Mr. Gamgee seemed to advocate light pressure by bandaging, not the firm pressure he formerly recommended. He agreed as to the importance of immobility in wounds of soft parts. Mr. Gamgee had hardly emphasised the advantage of drainage as much as he might have done. To secure free drainage was a most important indication, and caution should be used in dressing wounds in such a manner that free drainage was not permissible. Though not a "spray and gauze" man in any sense, yet he had faith in the action of the drugs known as antiseptics, which obviated the tendency to decomposition induced by water. Mr. Gamgee eschewed water altogether in dressing. He recommended also his principle of letting wounds alone as much as possible. The degree of elevation of temperature was as important an indication as persistence of elevation. Isolated rises were of little consequence. Persistence after the second or third day was of much consequence.—The PRESIDENT had for many years practised Mr. Gamgee's method, as a rule in private practice, and occasionally in hospital practice, although this was rather difficult in a hospital imbued with the doctrines of Listerism.—Mr. GAMGEE, in reply, said he did not trouble too much about the arrest of bleeding. He shut the wound up as quickly as possible, and under this system he never had secondary hæmorrhage. It was on accurately fitting universal pressure that he relied, not on localised hard pressure. He never sealed wounds without allowing free drainage. The washing of wounds should be as slight as possible; too much was injurious. He could find no difference, physiological or practical, between boroglyceride and glycerinum boracis (B.P.), with an excess of borax. He warmly advocated the study of Dr. Richardson's book on the healing of wounds, and mentioned certain facts showing the influence of mental excitement on the elevation of temperature in surgical cases. Many great operations were accomplished without any rise whatever. He treated private and hospital patients in precisely the same manner. The secret of Mr. Lister's success was the consummate skill and care with which those whom he had educated were trained to carry out their treatment.

#### EPIDEMIOLOGICAL SOCIETY.

A MEETING of this Society was held at University College, Gower-street, on Wednesday, November 1st, Dr. George Buchanan, President, in the chair.

Dr. NORMAN CHEVERS read a paper on the Sanitary Defects of the Site of London and its Environs, of which the following is an abstract. He was of opinion that notwithstanding all that modern land and town drainage had effected in the way of improvement, the most prevalent and worst diseases of the United Kingdom are due to the survival of thousands of acres of unreclaimed marsh land, and to the presence of thousands of miles of sewers, drains, and ditches, which retain, exhale, and exude as much as they void. The Celtic and Roman founders of London chose their position mainly because it was defensible in war, and

without any knowledge of the laws of malaria. The superficial geology of London may be represented by an oval cup of London clay and brick earth, extensively traversed and margined by marsh alluvium across the longer diameter, of which irregular heaps of more or less sandy gravel form a broken line of slight elevation. The greater part of Roman London was seated on good building ground. Originally marshes or swampy soil surrounded the entire land aspect of modern London, with the exception of an isthmus on the north-west. The whole line of the northern hills had, at its foot, oozy soil, into which the drainage of the uplands sank, to be only partially carried off by streams. The City was also protected on the north side by Finsbury and Moorfields, formerly a vast swamp. To the east London is bordered by the extensive marshes of the river Lea and the Thames, and east of these marshes extend vast tracts of the Essex and Kentish marshes, sixty miles to the sea. The Kentish marshes extend also to the south border of London, and those parts of the City now bearing the names of Bermondsey, Southwark, and Lambeth, were especially notorious, almost down to the present time, for the occurrence of ague, dysentery, and remittent fever, amongst the inhabitants. Originally the marshes westward were as injurious to the public health as those to the east; Westminster was almost an island even in Queen Elizabeth's reign, and St. James's Park was liable to be flooded up to 1682. Even now South Belgravia is threatened with inundation from the Thames. Northward of this part of London the ground is more or less elevated, and gravel and clay are found more abundant. Dr. Chevers next pointed out that much of the ground upon which houses are now, and have been for centuries, built consists of made earth; for instance, that in Finsbury-fields in 1549 one thousand cartloads of bones were deposited, and upon this was laid the soilage of the City, all of which has long since been built over. He then briefly alluded to the significance of the Anglo-Saxon word *ey* in many of the place names of London, as showing that the localities were originally paludal; and mentioned a few facts which indicated the great prevalence in old times, and as late as the end of the seventeenth century, of dysentery and intermittent fever in London. Dr. Chevers urged the necessity for a great national movement for the reclamation and utilisation of marsh lands near London, and that a Royal Commission should be appointed to inquire into the whole question and adequate funds raised. He believed trees might be planted on the Essex and Kentish marshes which would in a few years mitigate the severity of the east wind; that all kinds of manufactures not requiring night service might be carried on there; and that market gardens and reservoirs for fish for markets might also be made, and thus render the lands not only more salubrious, but more valuably productive than they are at present. He concluded by saying that every landlord should be under legal obligation to satisfy his tenant whether the site of his house had been a marsh, a brickfield, a burial-ground, or a plague pit; whether the house is built upon concrete, and whether there are diseased cesspools near the building. In the discussion which followed, the President, Sir Joseph Fayrer, Surgeon-General Hunter, Surgeon-Major Don, Dr. Thorne, Mr. Shirley Murphy, Dr. Henderson, Mr. Long, and Dr. Balfour took part.

#### NORWICH MEDICO-CHIRURGICAL SOCIETY.

THE first meeting of this Society was held on the 7th inst. at the Norfolk and Norwich Hospital, Dr. Barnes (Eye), the President, in the chair.

An exhaustive retrospective address of the work done during the past year was read by Mr. T. L. Lack.

Mr. F. C. BAILEY (Norwich) exhibited a specimen of a Double Fetal Monstrosity, united apparently by the sternum; the specimen was reserved for dissection in order to demonstrate the bond of union.

Dr. MCKELVIE (Cromer) exhibited a fibro-sarcoma of the neck removed post mortem; the tumour had existed about fifteen years; it measured 32 in. by 30 in., and weighed 17½ lb.

AN Exhibition of the International Inventors' Institute will be opened permanently on December 1st, 1882, from 9 A.M. to 5 P.M., free to the public, at Dashwood House, New Broad-street, London.

## ABSTRACTS OF

## INTRODUCTORY LECTURES

*Delivered in the Dublin Hospitals and Medical Schools,  
Session 1882-83.*

## ROYAL COLLEGE OF SURGEONS' MEDICAL SCHOOL.

MR. JACOB said that was an occasion of much importance to the College, and also of extreme interest to himself personally, for it was the first occasion on which he had assumed, in its full entirety, the mantle of his father. That day they inaugurated the last session of the hundredth year since the foundation of the College; and, moreover, on that day was to be opened the new school of anatomy attached to the College. They had, a few days since, initiated the first examination held under the new system, which they looked forward to as a regenerative step, and also legislation was impending, of which no one could tell the results, but which was fraught with important results to the College and to surgery in general. In a few words he then sketched the progress which had been made in Irish surgery down to the present time. In 1812 the first State grant was made, £35,000 having in all been contributed, and in 1828 the College was called upon by charter to support itself. A museum and laboratory were established by the College out of its own funds in 1835. In 1844 the apprentice system was reformed, and a supplemental charter was granted transferring the authority and power of the College from the censors and members to Fellows. The income of the College was £7000 a year, and it had a museum containing 7000 preparations, and a library containing 20,000 books, it being only second in the United Kingdom to the Hunterian library and museum in London. The lecturer concluded by referring in terms of praise to the new educational scheme of the College.

## MATER MISERICORDIÆ HOSPITAL.

MR. KENNEDY observed that clinical instruction can be but imperfectly understood if not preceded by a short preliminary course in the dissecting-room and in the physiological lecture hall. Anatomy and physiology form the basis of all medical and surgical knowledge, and are inseparable elements in the study of disease. To treat serious diseases, not knowing their history, their pathology, their progress, their dangers to life, and the sequelæ they may entail was in the highest degree culpable. The majority of the students, after completing the prescribed curriculum, would be commissioned by the State, either in military or civil life, to battle with disease, and frequently in quarters isolated, and perhaps often in cases of urgency beyond the reach of the immediate assistance of brother members of the profession. Let them picture to themselves the mental anxiety of a man possessing honesty or humanity who thus, unassisted, is called on to treat a rebellious disease. Each disease, or rather each division of diseases, would require the highest faculties of the mind to be put into constant and vigorous action, and applied unreservedly for a considerable time before they could effectively deal with any of them. A knowledge of fevers could only be acquired in the fever wards of a hospital, and the College of Physicians, showing their full appreciation of the subject, now requires a special certificate in the diseases referred to. The present member for Dublin was the author of a most valuable work on fevers, and to him they also owed the rejection of a Bill that, if once made law, would compel them to become the public informants of domestic affliction, and would destroy the confidential relations that exist between patients and their doctors. They all knew that the natural guardians of families were only too eager to adopt the sanitary suggestions of their medical attendants, and it could be easily understood how strongly they would resist, during a time of grief, the vexatious visits of sanitary inspectors. The medical gentlemen entrusted by the public with the health of the poor could do all that is necessary. Let the arduous labours of these gen-

tlemen be more fully appreciated and more generously rewarded, and let it be incumbent on them to report on the sanitary condition of the poor of their respective districts, and have power to remove any and every cause of contagion. To do more than this would be to increase the danger to the public health by inducing the concealment of contagious disease, and consequently, the neglect of the necessary precautions.

## ADELAIDE HOSPITAL.

THE inaugural address was given by Mr. KENDAL FRANKS, who hoped that the new session would be characterised by work, not the spasmodic effort that brought them to the ward to see a curious case, or to the theatre because a capital operation was about to be performed, but the honest work which was the outcome of a steadfast purpose, a determination not to rest satisfied with the dead level of mediocrity, but, by taking advantage of every opportunity which was afforded, to prove themselves fit to occupy a foremost place in the profession which they had chosen. In the wards they would learn what books could not teach, and what they learned there was that which they would value most hereafter. Other work neglected might sometimes be made up for by increased diligence afterwards, but the knowledge gained by daily contact with the sick could never be picked up by a system of cramming at the last moment. The object which they had in view was not merely to pass examinations and to become legally qualified. The profession which they had chosen demanded from them more than that. It required that when they had by law been declared competent to take charge of the lives of their fellow-beings, they should not be found wanting. He did not intend that morning to occupy their time by rehearsing the rapid strides which medicine and surgery had lately made, progress which would mark the nineteenth century as the most eventful in their history; but he would call their attention to one discovery which had done much to revolutionise both branches of their profession, and one which promised to show that, far as we have gone, we are still but children playing on the shore of an unknown and boundless ocean. He alluded to the germ theory. Hostile critics had brought every refinement of scientific research to bear upon it, but it stood the trial, whether of experiment, or the microscope, or the electric beam, and had emerged from the ordeal, no longer a theory but an established fact. In medicine it was now almost universally accepted. Fevers were no longer looked upon as smouldering fires that burnt up the system, or as humours devouring the frame; but were recognised as the result of a living "poison" that had been sown in the system, and had grown and multiplied during the stage known as the stage of incubation until it had poisoned the whole being. The organism which caused diphtheria, a form of what was called micrococcus, had been recognised, and its life history scanned. There was scarcely a malady which had hitherto so baffled the skill of the physician and mocked his every effort as the dreaded disease of hydrophobia. Yet the germ theory had shown the insidious poison which lurked within the system long before it attacked its victim. Experiments were being made to show whether by a process of inoculation after the victim had been bitten he might not be protected against the dreadful outburst of the disease. When this was established the germ theory and its development might claim a glorious triumph. The germ theory had recently been brought to bear on tubercular diseases. By a series of elaborate experiments Koch had at last discovered the source of this terrible scourge to be a micro-organism. He has isolated it, cultivated it, and inoculated with it. Was it too much to expect that as knowledge increases and earnest workers still labour on, some means shall be found for striking down the malady now dragged to light?

## RICHMOND HOSPITAL.

MR. THOMSON dwelt on the results of antiseptic surgery. There appeared, he said, at present hardly any part of the body too far removed from the surgeon's knife; but this would not have been possible had not the torch of medicine gone before to lighten the track they were to follow and make their way plain. It was in proportion as they advanced

in the knowledge of medicine that surgeons had been enabled to achieve the brilliant triumphs which made the nineteenth century the greatest in the history of surgery. But while much of this had been due to medical progress, there had been other causes at work not less powerful. The science of sanitation had been gradually operating in the same direction. Pure air, roomy wards, good food, the classification of patients suffering from infectious disorders, intelligent nursing, and all that was meant by cleanliness, had come to be regarded as contributing materially to the success of surgical treatment. Cleanliness in surgery was a term somewhat different in meaning from that ordinarily applied to it by the laity. It did not alone mean palpable concrete dirt, dusty floors, and dirty dressing, but it also signified the dirt which was impalpable—the dirt which only clung about the wards in the shape of viewless contagion, which was not less dirty though hidden from view. Under the old method of treating wounds the mortality was very high, but if they turned to the more recent developments of what was understood as antiseptic surgery, as taught by Lister, they would find a very great change indeed. He showed that in wounds or fluids undergoing putrefaction there were present certain organisms or germs, indefinite in structure, but definite in the outline, to be easily recognised by the aid of a microscope. He proved, as he thought indisputably, that if these germs could be excluded or their vitality destroyed when they made an incision into soft parts, and their access afterwards prevented by means of a dressing so prepared that all air passing through it must have its contained organisms killed, they could keep the wound antiseptic or unpoisoned, and thus reduce it to the state of a subcutaneous one. Mr. Thomson concluded by stating that at no time were there workers so many, so thorough, so industrious, and at no time had the demands upon energy been so urgent.

#### MEATH HOSPITAL.

AFTER some introductory remarks, Mr. SMYLY said he wished to tell the students what they intended to do for them, and what was expected from them in return. In the name of the Medical Board he promised that they would do all they could to impart what they knew, and in return they expected the students to learn what they could, always bearing in mind there was much in medicine and surgery which could not be explained to the ignorant, and there was much room in every branch of the profession for differences of opinion. Since they parted last summer great changes had taken place, not only in that hospital but in the profession. In the hospital the standing committee had expended a large sum of money in improving the sanitary condition of the house. Not long since every ward was in direct communication with the main drain, and the patients were constantly suffering from erysipelas and other forms of poisoning from bad air; but now all that was altered. They had now a clean and pure house, and bright and well-ventilated wards. The full acceptance of antiseptic surgery was a great step in advance, and they might now hope to see a succession of operations free from the horrors of blood-poisoning. Since they last met, the Royal College of Surgeons had instituted a new mode of examination, and instead of one final examination on most complicated and various subjects, they had in their wisdom substituted sessional examinations. In this way the process of testing the students' knowledge was brought into immediate contact with the process of teaching, and practical courses of lectures had been substituted for theoretical. He hoped this would be more fully carried out, and the yoke of compulsory attendance on lectures removed from the neck of the much-enduring student. The change made by the Royal College of Surgeons consisted in setting down certain definite subjects to be learned during the year, and the result to be tested by examination at the end of each term. It had been the fashion to run down a certain class of teachers—the so-called grinders—but he considered it was not just to do so, for they were the result of a system. General culture and athletic sports occupied very important places in the education of medical men. In adopting medicine as their profession they should always remember that they were walking in the steps of Him who went about doing good, healing the sick.

#### ST. VINCENT'S HOSPITAL.

DR. QUINLAN said that on that occasion they could hardly do better than consider recent researches upon infective zymotic disease, and the etiology of pulmonary consumption, a scourge to humanity, which up to the present had not been considered to be infective, but which had been proved to be so under certain circumstances. The whole subject was profoundly interesting and important, particularly in relation to the successful efforts which had been made for the attenuation and dilution of zymotic poisons—a plan which opened up a vista of preventive medicine of the most useful kind. The lecturer then described the various stages of zymotic diseases, and the experiments of pathologists which had revealed the true nature of those diseases. He referred to the investigations of Pasteur on the subject of chicken cholera, and the cultivation of the bacillus anthracis—the cause of aplenic fever in sheep—and of woolsorters' disease in man. Typhoid fever, he said, was popularly supposed to be due to bad smells and sewer-gas, but it was really due to the germs contained in these; and in reference to this there were two noteworthy points. One was that if sewage be poured through Italian rye-grass, the spongioles destroy all germs, and leave the resulting fluid so far harmless. The other was that, although germs will pass through the finest filters, filtration through spongy iron entirely destroys them. Up to a recent period it was generally believed that pulmonary consumption, although of a hereditary type, was not an infective disease. The matter had been set at rest by the discovery of Villemin that tubercle was inoculable, and this was followed up by Koch, who discovered the tubercle bacillus, cultivated it, and communicated it to animals. It was a consoling fact that tubercular bacilli, unless kept outside the body at a temperature of 100°, at once die, differing, fortunately, in this respect, from those of aplenic fever, which sometimes linger for years where animals were kept.

### Reviews and Notices of Books.

*A Dictionary of Medicine, including General Pathology, General Therapeutics, Hygiene, and the Diseases Peculiar to Women and Children.* By Various Writers. Edited by RICHARD QUAIN, M.D., F.R.S. London: Longmans, Green, and Co. 1882.

#### [FIRST NOTICE.]

THE generic term "dictionary" includes under it a great variety of learned works. Not only is it applied to volumes dealing solely with etymological subjects, but it is employed in medicine to such elaborate writings as are to be found in the "Dictionnaire de Médecine," the "Dictionnaire des Sciences Médicales," and the "Dictionnaire de Médecine et Chirurgie"—the composition of which, although placed in many hands, is the labour of a generation. Strictly such works deserve the title of cyclopædias, a term which is being now extended to works not completed in the alphabetical arrangement—as witness Ziemssen's "Cyclopædia of Medicine" and the American "Encyclopædia of Surgery" now in course of publication. The English works most allied in character to these latter are the *System of Medicine* and the *System of Surgery*, edited by Dr. Reynolds and Mr. Holmes respectively. In all these works the idea of co-operation in their composition has been fully carried out—a plan absolutely necessary in the present day, when medicine has extended its limits so widely. One of the first books published on this plan was the well-known "Cyclopædia of Practical Medicine" projected by Dr. A. Tweedie, and edited by him in conjunction with Drs. J. Forbes and Conolly. Some of our readers may remember the issue of this work, which came out in parts in the years 1833 to 1835, and which numbered among its contributors some of the leading physicians of the day. Among them there still remain with us Drs. Tweedie, Bisset Hawkins, and J. C. B. Williams. It was very popular with the profession, the

edition, which was a large one, being completely disposed of, but yet it is a work which is now almost forgotten and seldom referred to, sharing in this the fate of the equally well-known "Cyclopædia of Anatomy and Physiology" edited by Dr. Todd. Such works remain, however, to mark the state of medical knowledge of their time, and they contain much that is of permanent value. The "Cyclopædia of Medicine" opened with an article on the History of Medicine from the pen of Dr. Alison, and closed with a bibliography, which seems meagre nowadays as contrasted with the bibliographies of the modern French dictionaries referred to above.

Turning now to works less extensive and elaborate, and planned more upon the lines of the one under review, it is interesting to find the same conception carried into execution by an Englishman one hundred years ago. There is before us as we write a folio dated London, 1775, which has the following title: "A New Medical Dictionary or General Repository of Physic, containing an Explanation of the Terms and a Description of the various Particulars relating to Anatomy, Physiology, Physic, Surgery, Materia Medica, Pharmacy, &c. &c.; each Article, according to its importance, being considered in every relation to which its usefulness extends in the Healing Art. By B. G. Motherby, M.D." We know nothing of the author of this work beyond what may be gathered from its pages, but we should imagine that this constituted the first real attempt in our language to collate the facts of medical science in the form of a dictionary. Nor is it simply a lexicon of terms, many of the articles being of considerable length. It is interesting to note how many terms then current have fallen into desuetude, and how many remedies then in vogue have been abandoned, whilst the descriptions of disease and the interpretation of symptoms might have been written in the time of Hippocrates. A comparison of this work with the present "New Medical Dictionary" shows strikingly the great advances made in medicine during this century. We have, however, opportunities of comparison, not with a work published a century ago, but with one the appearance of which is separated from us by barely a generation—that, namely, to which the late Dr. Copland devoted the best years of his life. His Dictionary was in many respects unique. Its publication extended over fourteen years (1844 to 1858), whilst its compilation was the labour of thirty years. It may confidently be predicted that no single individual will ever again attempt such a task. No single intellect can deal adequately with the whole science of medicine and its numerous branches, and no amount of study will enable a man now to succeed in such a task to the extent that Copland succeeded in his day. Although an abridged edition of his work was issued so recently as 1860, it, like the Cyclopædia, has now but few readers. It has simply fallen "out of date"—a fate which necessarily comes to all such compilations in process of time, and the sooner when the subjects with which they deal are in a state of transition. For the utility of dictionaries of science, as indeed of all systematic treatises upon subjects which are constantly expanding, is almost limited to the years of their appearance; and the main difficulty in all such works is to ensure that on their publication they shall be abreast of the time. For all that, one cannot but admire the patience and learning of the man who did what Copland did; and we may be permitted to quote the following tribute, which is to be found in the Roll of the Royal College of Physicians. Speaking of the Dictionary and its author, Dr. Munk says:—

"Considered as the production of one man, this work is one of the most extraordinary that has ever appeared for its size, comprehensiveness, accuracy, and learning, and although necessarily inferior in certain respects from its very plan to some works of a like kind, the composition of a large body of writers associated for the purpose, it is superior to these in the general unity of the principles and practice laid

down in it, and assuredly excels them all in depth and variety of research. The information amassed in these volumes is literally enormous, and must excite astonishment as the production of one individual; but when it is further considered that the whole of the materials were most carefully selected from all existing sources, most patiently digested, elaborated, and arranged into compact and simple forms easily accessible and readily available, it is not easy to point out in the whole of medical literature any work by a single hand so much calculated to excite admiration of the industry and talents of the author. In every article contained in the volumes the reader cannot fail to be struck with the writer's most extensive learning, which has enabled him to collect knowledge from all authorities, ancient and modern, foreign and domestic, and he will, at the same time, be no less surprised than gratified at the singular power which has arranged the whole so lucidly, and in such systematic order. Thirty years of Dr. Copland's life were devoted to the Dictionary. He laboured on it alone and unassisted. His labours, which he tells us were incessant for many years, were persisted in under circumstances and contingencies which few could have endured. He received no assistance in furtherance of his undertaking, nor, as he adds, with his knowledge of human nature, could he have accepted any."

It is time to turn to the work before us that has just been published by Messrs. Longman. It is a bulky volume of upwards of 1800 pages. It is now many years since it was first projected, and its appearance, long expected as it has been, must be a great source of relief and gratification to those concerned in its production; particularly to the editor's able coadjutors, Drs. F. T. Roberts and Mitchell Bruce, whose names in our opinion should have appeared on the title-page, and upon whose shoulders so much of the labour of its compilation has devolved. The task these gentlemen have had so long in hand was no easy one, for besides the work of collecting, editing, and supervising contributions, no doubt excising redundancies and making needful additions, they have themselves had to contribute largely to the text of the volume. We may assume that they furnish all those articles that require no detailed exposition, all those to which no signature is affixed, whilst they appear as signed contributors to upwards of 120 articles, some of considerable extent and research; as the articles on Anæmia, Morbid Conditions of the Blood and on Rheumatism by Dr. Bruce; on Gout by Dr. Roberts.

In carrying out the plan of the work they have been ably aided by a host of writers, physicians and surgeons, the work being distributed mainly amongst those who have paid special attention to the various subjects dealt with. To give only a few instances. Sir James Paget contributes an article on Pathology and another on Symmetry; Sir W. Jenner writes on Deformities of the Chest; Drs. Bastian, Buzzard, Gowers, Ferrier, Brown-Séquard, and Long Fox on Diseases of the Nervous System; Dr. Broadbent on Fever and some of the Specific Fevers, as well as on Chorea; Dr. Grainger Stewart on Bright's Disease; Dr. Murchison, Legg, and Ward on Diseases of the Liver; Drs. Allchin and Oliver on Diseases of the Stomach and Intestines; Mr. Durham on Intestinal Obstruction; Dr. Lauder Brunton on Pathological Chemistry, including the Urine; Dr. Parkes on Public Health; Mr. Netten Radcliffe on Epidemics, Plague, &c.; Miss Nightingale on Nursing and Nurses; Drs. Green, Powell, Waters, and Symes Thompson on Diseases of the Lungs. Sir Erasmus Wilson takes the main share of Diseases of the Skin, a few articles being contributed by Drs. Tilbury Fox, Liveing, and Sparks; Mr. Simon writes on Contagion; Diseases of the Eye are dealt with by Messrs. Carter, Streatfeild, and Nettleship; of the Ear by Mr. Dalby; Diseases of the Heart by Drs. Bruce, Bristowe, Quain, Shapter, and Wardell; of Aorta and Aneurism by Dr. Hayden and by Mr. Holmes. Dr. H. Weber writes on Hydrotherapeutics; Drs. Stevenson, Poore, and Ferrier on Medico-legal Subjects and Toxicology;

whilst Surgical subjects are dealt with by Messrs. Gascoyen, Callender, Hutchinson, Durham, Holmes, M. Beek, and Godlee; Gynæcology by Drs. Barnes, Playfair, and Herman; Diseases of Children by Dr. Eustace Smith; subjects of General Pathology and Morbid Anatomy by Drs. Cayley, Payne, and Gee, whilst Professor Greenfield contributes articles on Micrococci and Malignant Pustule. In fact this summary, incomplete as it is, and written after a general survey of the work, suffices to inform us that the principles of selection of writers were discriminating and judicious; and much of the success and permanent value of the work will rest on them. It would be obviously impossible to attempt a thorough and critical survey of this work of many hands; but all we propose to do in this and the succeeding notice is to select a few of the more important articles to show our readers what to expect within the pages of this bulky volume. In fulfilment of this intention we may just glance at the work of those contributors who have passed away since they penned the articles which remain as the final mementoes of their labour. It is sad to find that one-tenth of the whole band has thus departed, and it seems but due to them that we should notice their work first before proceeding to that of those who remain.

The subjects of Abdominal Aneurism, Diseases of the Aorta, and Thoracic Aneurism are contributed by Dr. Hayden, and are marked by the thoroughness and care with which his large work on Diseases of the Heart is characterised. Of all methods of treatment of aneurism he gives the preference to that of rest and restricted diet; but he does not omit to state that surgical measures have in some cases proved successful; whilst he mentions such medicinal remedies as iodide of potassium, aconite, and ergotine injections, so much approved by some. Dr. Peacock goes over ground well trodden by him before in the articles on Congenital Misplacements and Malformations of the Heart; he also contributes the article on Influenza. Dr. Murchison in like manner deals with Jaundice. Sir J. R. Cormack treats of Croup, Diphtheria, and Diphtheritic Paralysis; and in the first-named article he clearly shows that membranous croup is not the product of simple acute inflammation, but agrees with French writers, with G. Johnson, Jenner, and others, in regarding it as due to the diphtheritic poison. These articles are well worth reading and pondering; for they exhibit in a small compass the solution of many difficulties. Dr. Lockhart Clarke contributed the articles Infantile Paralysis, Locomotor Ataxy, and Progressive Muscular Atrophy, which are detached, perhaps unwisely, from the series of articles on Diseases of the Spinal Cord, contributed by Dr. Bastian. We do not think sufficient stress has been laid by the lamented *savant* upon the "gastric crises," and the joint affections of ataxy, and could have wished that each of these articles had been more thoroughly revised than appears to have been the case. No better choice as the writer upon Anæsthetics, Artificial Respiration, and Resuscitation could have been made than that of Mr. Clover, whose remarks on these subjects will be read as embodying the fruits of a wide experience. The paper on Causes of Disease, by Dr. Pearson Irvine, is a model of systematic writing, and full of suggestiveness. Dr. Parkes has contributed the article on Public Health, which occupies fifteen of these closely printed pages, and deals with the subject as regards—(1st) cities and towns; (2nd) villages; (3rd) houses; ending with remarks on vital statistics. A few additions have been made to the article by Dr. Buchanan. Dr. Seaton writes on Vaccination, and medical men will do well to study this concise statement of the undoubted efficacy of the measure from so high an authority. This article has been revised by Dr. Collie. Dr. Sparks devotes several pages to the important subject of the Treatment of Disease by Climate, and also contributes

papers on certain skin affections, as Lupus, Pemphigus, and Purpura. Dr. Silver gives a clear and accurate description of Addison's Disease, and also a short article upon Suprarenal Capsules. The same writer deals in an excellent manner with Diabetes Mellitus; but here, again, we are reminded of the rapid progress of science, in that we find no mention made of lipæmia and fat-embolism, as a cause of so-called diabetic coma; or indeed of any detailed reference to this latter termination (one of the most frequent in the disease) at all. Dr. Stephen Ward contributes papers on certain diseases of the liver—e.g., Albuminoid Disease, Enlargement, Fatty Disease, Functional Disorders, and Hydatid Disease; Dr. Tilbury Fox writes a few short paragraphs on certain skin affections—e.g., Dysidrosis, Impetigo Contagiosa, Epiphytic Skin Diseases, and Tinea; and Mr. Harry Leach has articles on Quarantine and Scurvy. The names of two surgeons close this list—viz., of Mr. Callender, who contributes the articles on Abscess; and of Mr. Gascoyen, those on Diseases of Cartilage, Condyloma, Fumigation, and Mucous Tubercles.

### "POISONING FROM BRAWN."

To the Editor of THE LANCET.

SIR,—In connexion with the notice in an article in your issue of the 11th inst., of a report by me of a series of cases with severe gastro-intestinal disturbance following the consumption of pork, you will perhaps allow me to state that since the report in question was written I have had the opportunity of comparing the micro-organisms therein referred to with drawings of those found by Dr. Klein, in the well-known Welbeck ham-poisoning cases, and engraved in the last Report of the Medical Officer to the Local Government Board; and that in both cases the bacilli appear to be morphologically identical. I am quite aware of the unreliability of conclusions as to the nature of bacilli, drawn from considerations of form alone, but with this reservation, the identity in the two cases goes far to prove the specific nature of the disease. I have placed some mounted microscopic specimens obtained from the brawn which produced the symptoms at the disposal of the Local Government Board, in case it should be thought worth while to obtain the opinion of the original observer of the bacilli in the Welbeck cases as to the identity of the micro-organisms in the two cases. These outbreaks are not only most interesting from a pathological point of view, but of some importance from a medico-legal one. As in the two fatal cases, which occurred in the first series of cases reported by me, the illness was so sudden and short, and the symptoms so much resembled those of irritant poisoning, that a coroner's inquest was held in both cases.

I am, Sir, yours, &c.,

Shrewsbury, Nov. 15th, 1882. W. N. THURSFIELD, M.D.

THE CASE OF DR. ABRATH.—At Westminster, in the Court of Queen's Bench, before Mr. Justice Field and Mr. Justice Stephens, Sir H. Giffard has moved, on behalf of the plaintiff in the case of Dr. Abrath and the North-Eastern Railway Company, for a rule nisi for a new trial, on the ground that the verdict which was given for the defendants was against the weight of evidence, and on the ground of misdirection. Their lordships granted the rule asked for. It will be remembered that the action respecting which the rule was last week asked was one brought by Dr. Abrath against the North-Eastern Railway Company to recover damages for alleged malicious prosecution respecting his treatment of a patient, who subsequently recovered damages for injuries sustained in a collision on that railway.

THE THIRLMERE WATER SCHEME.—The award in the suit brought by Countess Ossalinsky, the proprietor of land at Thirlmere, against the Corporation of Manchester, has been announced. The arbitrator finds the Countess entitled to £64,445, and a sum of either £6000 or £4000 additional, contingent on the view that may be taken of a special point in the case.

# THE LANCET.

LONDON: SATURDAY, NOVEMBER 18, 1882.

WITH the general purport of Mr. CHURCHILL'S letter on the subject of Children's Diseases being made a Specialty at General Hospitals (published in our present issue) we heartily agree, although we cannot subscribe to all the arguments set forth, some of them appearing to us, in fact, rather irrelevant. Amidst the various contending views as to the proper plan of medical education, it is very necessary to bear in mind the commonplace requirement that a medical school ought to equip a man as far as possible with the necessary knowledge and skill for general practice. On the whole, it is perhaps for the best that the old apprenticeship system is rapidly passing away. But in trying to substitute more scientific methods, it behoves us to endeavour to retain as far as may be its special advantages, amongst which may be reckoned the familiarising the student with the symptoms and treatment of simple everyday complaints. A considerable proportion of the general practitioner's daily work consists in midwifery and the treatment of the ailments of children. With the first we are not at present concerned; but as to the second, it must be confessed that many a distinguished graduate has found himself launched in practice and very much at sea in the simple routine of examining children and prescribing for them.

One point to which Mr. CHURCHILL refers—viz., the testimony of students who have held even for a short period clinical appointments at children's hospitals—is certainly worthy of attention. It would indeed be well for us, in regard to the subject of this letter and many other defects of medical education, if we could take into our councils some of our best young general practitioners. Many men, both old and young, give up in despair the complete physical examination of a child who begins to cry, and thus it happens that often an empyema is allowed to go on unchecked, and cases of severe heart diseases to drift on unsuspected by men who in regard to adults would be incapable of flagrant blundering. The prompt recognition, and, what is more to the point, the reasonable suspicion, of the on-coming acute specific diseases, is one of the lessons which a man has mostly to learn for himself, sometimes at the cost of much chagrin and damage to his early reputation. Finally, in all that concerns the bringing up of infants and children the young doctor starts in practice often woefully ignorant. In the lying-in room the baby is consigned to the care of a monthly nurse, who is often obstinate and conceited in proportion to her ignorance. On any question of feeding, or washing, or clothing, the young doctor's advice is seldom asked, and probably with good reason, for he knows little more about an infant than about a puppy, and his solitary notion is often that it should be kept covered up. With regard to older children, the *laissez faire* method of many medical men on the subject of keeping the neck and extremities warm, the use of cold or

warm baths, the kind of food and the intervals between meals, and a score of other points in which mothers ought to have guidance, deserves only to be mentioned to be condemned.

It is obvious from these and many other illustrations which might be given that some more complete practical instruction is needed in our medical curriculum with regard to children's diseases. It may also be added that a properly organised children's department is of the greatest possible value, from the teacher's point of view, for demonstrating clinical medicine. With a little tact, which every man ought to acquire, a child may be examined in such a complete way as is scarcely practicable with regard to adult patients. For exercise in the study of what is called the "facies" of disease, children are quite invaluable. Further, in many of their acute ailments we may with a good conscience watch the spontaneous tendency to recovery untrammelled by drugs, and in many of their chronic diseases we have excellent material for testing the beneficial action of therapeutic remedies.

In some of the general hospitals there are already children's wards, and the real question at issue is, How can they be best utilised for teaching purposes, and not merely for a convenient classification of patients? We quite agree with Mr. CHURCHILL'S view, that for teaching purposes the nominal association of midwifery and gynecology with children's diseases should be severed. The association has long been obsolete in fact, and ought no longer to be maintained on the prospectuses. There is a real danger, then, of the proper teaching of this department being left out in the cold. Ought a special physician and a special surgeon to be devoted to it, or should each member of the senior medical and surgical staff have his allotment of children's beds? For our part we incline to the first plan, subject to rearrangement at definite intervals, so that each officer may in his turn have for a time full control of the medical or surgical children's beds contemporaneously with adult cases, it being understood that during his tenure of office a separate clinique is made of the children's department. It is never to be forgotten that the members of a hospital staff need constant education alike with the students, in order to keep their knowledge and methods broad as well as deep. For this reason, although we strongly approve of special departments, we look with much apprehension on the further increase of specialists at hospitals.

In regard to the out-patient children's practice, which, from the practitioner's point of view, is quite as important as the in-patient work, we hold that there ought to be at every general hospital a separate day at least once a week for children's cases only. This might be taken by one of the assistant-physicians and one of the assistant-surgeons, just as in some of the hospitals the throat cases and skin cases are taken by members of the staff in turn, without relinquishing their general work.

Thus, with a special clinical course on children's diseases, and an out-patient day for children's cases, we believe the general hospitals might fairly meet the needs of the student in this direction. We should deprecate the giving a course of systematic lectures on children's diseases, because they ought not to be severed from the course of general medicine, and the multiplication of systematic lectures is a weariness

to both students and teachers. We also fail to see the advantage of a rigid classification of medical and surgical diseases from which Mr. CHURCHILL seems to expect such great things. We think that, in the interests of the patient, and for the furtherance of knowledge, the boundary line should be a very elastic one, and with regard to children more even than with adults, because in them disease is so much more generalised.

THE path of experimental inquiry into the nature of puerperal septicæmia is beset with many difficulties. The disease is, unhappily, not rare, but its occurrence is usually under conditions which do not facilitate experiment, and the results obtained are always incapable of strict verification. The circumstances of the origin of the disease, and its intensely contagious character, leave little doubt of its dependence on an organised virus, and when our investigations into the nature of bacteria are more complete, important additions to our knowledge of the character, forms, and origin of puerperal septicæmia may be looked for. The presence of organisms in the disease has been abundantly demonstrated. WALDEYER found that the peritoneal liquid was simply an emulsion of bacteria, and in animals inoculated with this the same bacteria were found; and HEIBERG, as long ago as 1873, maintained that the system was invaded with bacteria from the uterus in all infectious forms, whether purulent lesions were produced in the body or not. STEURER traced lymphatics filled with bacteria, from a diphtheroid path in the vagina, as far as the diaphragm and the pleura. An important step in the investigation was made by DOLERIS under the direction of PASTEUR. He examined the lochial discharges, and the blood, of puerperal women, and cultivated artificially the organisms which he found. In the former were many species of bacteria, the large bacteria of suppuration, and the bacterium termo, both aerobic forms, needing an oxygenated medium for their existence, and causing no serious danger to patients. They grow in the neighbourhood of the external genital organs, and are rare in the deeper parts. On the vulva were also micrococci, single, double, and in chaplets, some minute, others larger, and probably of a different species, since they are rarely met with in series. The organism which DOLERIS believed to be the real agent of puerperal septicæmia is a special form, anaerobic, developing in media which contain little oxygen, and best in those in which there is none. It is rarely met with at the vulva, but is usually abundant in the deeper genital parts. When the sequelæ of labour are normal, the lochial discharge contains none, or almost none, of these organisms, but they are never absent in the fetid discharge, and in women who have died from puerperal fever they are scattered abundantly in all the tissues, and especially in the lymphatics. He believes that in the rapid form of septicæmia, which kills in three or four days, the blood contains two forms of bacteria, rod-shaped elements in addition to the septic form; but when the disease has a longer course, micrococci are abundant in the blood in different degrees of evolution. When there is suppuration, whatever the position of the pus, whether in veins, joints, or on a serous membrane, pleura or peritoneum, the double micrococcus predominates. The blood, however, does not seem to be a very

suitable medium for the growth of microbia. They only grow actively when they are still, or almost still. In the vessels they are only abundant at the seat of a thrombus, but the lymphatic system is that in which their development is most rapid, whence they come into the blood, and pass into the viscera, and the rapidity of their development in some cases appears to be almost inconceivable. Out of the body they lose their virulence after the third culture. To some extent the researches of DOLERIS have been confirmed in Italy by MASINI and FERRARI. They believe that the infective agent is a "vesicular" body, pyriform and punctiform, which is constantly found in the blood of patients suffering from the disease, and is also reproduced in animals, to which the malady is communicated by inoculation. The rods are only met with in cadaveric liquids.

MASINI believes that these organisms are not peculiar to the puerperal forms of septicæmia, but that the same elements occur in other septic processes. This opinion is also held by the distinguished investigator of Lyons, Professor CHAUVEAU, who is conducting an extensive series of experiments regarding puerperal septicæmia, from which we may hope to gain, before long, new and important facts relating to the disease. At present he has only described (to the Société des Sciences Médicales at Lyons) certain preliminary results which he has reached. It was discovered by D'ESPINE in 1873 that rabbits are particularly prone to suffer from the infection of puerperal septicæmia. In this respect they present a striking contrast to guinea-pigs, which resist the infection, although so susceptible to other forms of blood-poisoning. D'ESPINE showed that if pus from a case of puerperal peritonitis is injected into the vagina of a pregnant rabbit, a condition is produced apparently identical with puerperal fever in the human subject. HAUSSMANN, repeating these experiments, has ascertained that the injection causes no symptoms if the period of gestation has not exceeded fifteen days, but after this period abortion is certain, and is followed by septicæmia. If serum from one rabbit thus dead be injected into the gravid uterus of another, the effect is still more rapid; the animal dies in a few hours, without any purulent exudation into the peritoneum. Rabbits have therefore been employed by CHAUVEAU in his experiments. He has succeeded in producing every known degree of puerperal septicæmia, grave and benign, acute, subacute, and chronic. He does not find, when the virus is injected into the tissues, that the condition of the animal has any influence on the result. He has succeeded equally well with males and females, and with young animals and old; in all the symptoms and lesions observed are nearly the same. Nor does he find that the condition of pregnancy materially influences the result, although, towards the end of gestation, or after delivery, the peritoneum seems to inflame rather more rapidly. The result varies a little, however, according to the mode by which the virus is introduced. If the injection is into the peritoneum, a purulent infiltration forms in the skin around the point at which the needle perforated it, and may remain for several months. Death usually occurs in five or six days from the time of the inoculation. Peritonitis, more or less severe, is always present. There is much effusion, containing large numbers of the special micrococcus, sometimes single, sometimes double. The peritonitis was usually associated with double

urisy and pericarditis. The cutaneous lymphatics near point of inoculation are full of pus, and the nearest lymphatic glands are also purulent. If, however, the animal dies very rapidly, in less than twenty-four hours, no peritonitis may be found, although the blood contains the infective micrococci in great abundance. These seem to grow especially in the branches of the portal vein, for blood taken thence possesses extreme virulence. An injection of the virus into the subcutaneous tissue of the abdominal wall gives nearly the same results. Sometimes, however, it is ineffectual; occasionally death is extremely rapid; and, as a rule, wherever the microbes penetrate suppuration occurs. An injection into veins causes no local inflammation. The animals die from the general infection, and the only lesion usually found is congestion or extravasation of blood in the lungs.

A remarkable fact was ascertained in the case of three rabbits, which, although suffering from the effects of the inoculation, ultimately recovered, at least partially. They appeared to have acquired a perfect protection from the disease. It was impossible to produce in them experimental septicæmia. They had undergone, as it were, a septicæmic vaccination. This result naturally led CHAUVEAU to endeavour to obtain a benign virus, which might confer immunity without causing a dangerous illness. He is now making experiments by the method of the attenuation of virus employed by TOUSSAINT, which consists in submitting it to the action of heat. The results of the experiments are not yet sufficiently complete for publication. The fact remains, however, that one attack of puerperal septicæmia protects a rabbit from another. It cannot yet be affirmed that this is true also of the human subject, but CHAUVEAU believes that there are some facts which point in this direction.

THE recently issued report of the Commissioners in Lunacy dealing specially with the statistics of lunacy as recorded on January 1st last, shows that both the number of the registered insane and their ratio to population exhibited a further increase during last year. The number of the insane of all classes had advanced to 74,842, against 36,762 in 1859, the first year embraced by the statistics of the Commissioners. The proportion of total lunatics to population had increased in those twenty-three years from 1·87 per 1000 to 2·83. These figures show that the amount of recorded lunacy, after due allowance for increase of population, was 52 per cent. greater on the 1st of January last than it was twenty-three years previously. As the numbers here dealt with include lunatics of all classes, pauper and private, and those residing with relatives or in workhouses, as well as those detained in public asylums or in licensed houses, no amount of interchange between these classes can of itself account for this steady increase in the number and proportion of registered lunatics. The figures support the conclusion that the recorded increase of lunacy is due to the accumulation of pauper patients in asylums rather than "to an annual production of fresh insanity disproportionate to the yearly increase of the population." It is true that the recent increase has occurred exclusively, and the increase since 1859 has been mainly, among pauper lunatics. It is also true that the proportions of pauper lunatics in asylums, in workhouses, and residing with relatives and

others, have shown a marked change during the past twenty-three years. In 1859 18 per cent. of pauper lunatics resided with relatives and others, whereas on 1st January last only 9 per cent. received out-door relief. The proportions in workhouses in 1859 and 1882 were almost identical, but as the large metropolitan asylums for imbeciles at Levensden, Caterham, and Darenth are legally classed as workhouses, the proportion of the insane in workhouses proper has really declined. The proportion detained in asylums has increased from 57 per cent. in 1859 to 66 per cent. in 1882. The actual result of the influences constantly tending to bring out-door lunatics into workhouses, and to transfer lunatics from workhouses to asylums, has been a net transfer of 9 per cent. of the registered pauper lunatics from out-door residence into asylums. It is obvious, however, that such transfer *per se* will not account for the steady increase in the aggregate amount of these three classes. The accumulation theory requires further definition and elucidation. It is quite possible that the present registration of the insane, by the various authorities responsible for their care or treatment, is more complete than it was twenty-three years ago. This may account for some of the recorded increase. Apart, however, from this source of explanation, the only apparent source of the accumulation by which it is sought to explain the apparent increase of lunacy is the decline in the death-rate of the increasing proportion under treatment in asylums, compared with that which prevails among the decreasing proportion in workhouses, and residing with relatives and others. Here, unfortunately, the statistics of the Lunacy Commissioners fail to supply the necessary facts for estimating the results of accumulation arising from this cause. No figures are given showing the death-rate among the insane, either in workhouses or residing with relatives and others. The Local Government Board are, we presume, primarily responsible for this important omission. The figures are, however, absolutely necessary for testing the real value of the accumulation theory as an explanation of the constant increase in the proportion of total lunacy. We fully believe that accumulation is taking place in our asylums, and that it is largely due to the cause above-mentioned, but further statistics are necessary to establish the theory, as well as the extent of its operation. In connexion with this subject we published a few years since some elaborate statistics of mortality in the Metropolitan Asylums for Imbeciles, showing that the death-rate in those institutions, which averaged 140 per 1000 in the first three years of their existence, declined to 82 in the three years 1877-79. These figures afford ground for concluding that much accumulation of so-called lunacy would have been prevented if the metropolitan imbeciles had been left in the imbecile wards of the metropolitan workhouses. We want, however, further facts in this direction.

It is not to be doubted that the Committee of the Royal College of Physicians, to which the consideration of Dr. ACLAND's resolutions has been referred, will realise the great responsibility which will be incurred by the College if it seems to take a step which may be misconstrued. We do not doubt at all that, with the known views and dispositions of the two English Royal Colleges, it would be very easy to construct a Board of Examiners that would

amply satisfy public and professional opinion, and the creation of which would be a great and long-deferred boon to unfortunate students who have two boards to pass where they should have only one. As we said last week, such a board might go far to solve the vexed question of a Conjoint Board "so far as England is concerned." But this is saying very little indeed. It is not an English problem that calls for solution; it is a British one. It is that there are irrepressible rumours of the inequality of examinations that ought to be above all suspicion of inequality; and that the members of the profession holding diplomas from one part of the country are told by leading members of the Medical Council, by the Medical Council itself, and by the Royal Commissioners, that the examinations they have passed are "too elementary," and that the diplomas they possess afford no guarantee of a competent knowledge of medicine, surgery, and midwifery. What cure for these complaints and evils will there be in the creation of a good board merely in one division of the kingdom? Absolutely none; but only a greater probability that students will be driven to boards in other divisions where, it may be thought, things are conducted more easily and cheaply.

The resolutions of the Royal College of Physicians set great store on the authority of the Royal Commission. Yet we have great misgivings as to whether the College, in entertaining these resolutions, is acting loyally either to the Royal Commission or the Government. Surely it would be a higher course in the English Royal Colleges, which have throughout these controversies displayed more public spirit than their sister Colleges, to go to the Government and say that they are fully prepared to subordinate their interests to the main recommendations of the Report, provided that the corporations in other parts of the kingdom do the same. It may be said that a conjunction of the two English Colleges will in no way place them in a worse position if the Government should introduce a Bill. Perhaps not. But what is wanted is compulsory legislation without delay. The energy of the Colleges should be directed to this end, and to the termination of this intolerable state of suspense and mutual disparagement. The two Royal Colleges of England owe it to themselves not to be led off the track of thorough reform by Dr. ACLAND, who has always been timid and temporising in this matter. It will be a great disappointment to the profession if the College of Physicians, with Sir WILLIAM JENNER at its head, who has been more thorough and more in sympathy with the profession than any of his colleagues, takes a step which will be misconstrued, if it is not initiated, by the enemies of reform; just at the moment when it is commended by a Royal Commission.

THE following standing rule of the Royal College of Surgeons has just come into operation, and will no doubt stimulate students to be better prepared for the membership of the College:—"When a candidate referred on the Pass Examination for the diploma of member shall have exhibited such extreme ignorance in the examination as, in the opinion of the Court of Examiners, to render it desirable that he should be referred for a longer period than six months, he shall, before his admission to re-examination, produce a certificate of having attended the surgical practice and clinical lectures on surgery of a recognised hospital for a further period of nine or twelve months, as the Court shall determine."

## Annotations.

"Ne quid nimis."

### ROYAL UNIVERSITY OF IRELAND.

AT a recent meeting of the Senate the following alterations as to the courses for medical examinations were adopted:—  
1. As to certificates of acquaintance with mental diseases, candidates will not be required to produce certificates of having attended courses of lectures on these diseases; but every candidate for the M.B. degree will be required henceforth to produce a certificate of attendance for three months in a recognised lunatic asylum, where clinical instruction is given. 2. After the year 1883, all candidates for the degree of M.B. will be required to exhibit proficiency in the use of the ophthalmoscope and laryngoscope. 3. After the year 1883, all candidates for the degree of M.Ch. will be required to present a certificate of having attended a three months' course of lectures on operative surgery. 4. After the year 1883, all candidates for the degree of M.Ch. will be required to pass a special written examination. In 1884, a studentship will be awarded for proficiency in experimental physics and chemistry, and the following year for proficiency in biology (including physiology, zoology, and botany), and in geology (including mineralogy and physical geography).

### NYCTALOPIA AND HEMERALOPIA.

Two interesting etymological papers appear in the tenth volume of the Royal London Ophthalmic Hospital Reports, from the pens of Dr. Greenhill and Mr. Tweedy, with the object of fixing the signification of the terms *nyctalopia* and *hemeralopia*. These terms were in use at a very early period of medical history, and one of them, "*nyctalopia*," was used, and in one passage defined, by Hippocrates himself. It is natural, then, to inquire what his definition was, and it appears that in all the older editions of his works the passage runs, "Οἱ δὲ τῆς νυκτὸς ὁπῶντες, οἱ δὲ νυκτὸς καλεόμεν, κ.τ.λ." ("Those who see at night, whom we call *nyctalopes*.") But in 1864 Ermerins, in his splendid edition of Hippocrates' works, considered the passage in question to be corrupt, and that the word *οὐχ*, "not," which of course entirely alters the sense, had been accidentally omitted. Dr. Greenhill supports Ermerins' emendation, on the grounds, first, that one of the MSS. of the Hippocratic writings in the great library at Paris had originally the word *οὐχ* before *ὁπῶντες*, which, though erased, is still plainly visible; and secondly, Celaeus, in translating this passage of the "*Prorrhetica*," gave the signification night-blindness to it. Galen again, in the latter part of the second century, interpreted *nyctalopia*, as used in the Hippocratic collection, to signify night-blindness, and therefore clearly held the true reading to be *οὐχ ὁπῶντες*, though in works deemed on other grounds of doubtful authenticity he is made to use the word in the sense of day-blindness. Galen also makes a comment upon the sentence which shows that he regarded the word as compounded of *νύξ*, "night"; *δαός*, "blind"; and *ὤψ*, "eye." After Galen, Orbasius, Aëtius, and Paulus Aegineta, to whom other names of great weight might be added, employed the term *nyctalopia* to signify night-blindness. But Mr. Tweedy supplies additional evidence in support of the emendation of the ordinary text of Hippocrates, drawn from a consideration of the medical aspect of the cases to which the term is applied. Thus he points out that the affection was described by Hippocrates himself as occurring especially in children and young adults; in those who have dark eyes and small pupils, whilst it is exceptional in married women and in healthy maidens; that it was customary for eruptions to appear about the ears on the seventh or eighth day; that the formation of abscesses

and spontaneous diarrhoea are to be regarded as favourable prognostics; that the treatment should consist of bleeding, cupping, purging, and the ingestion of the liver of the ox steeped in honey; and lastly, which is of great importance, that the disease may be complicated with swelling of the gums, bleeding from the nose, ulcers on the legs, and enlarged spleen—in a word, with the symptoms of scurvy, which is just the condition in which night-blindness is apt to occur. Mr. Tweedy has further drawn up a table from which we learn that, except in the disputed passage of Hippocrates quoted above, and in the doubtful Galenic work, no author of repute used the term "nyctalopia" to denote *day*-blindness before the seventeenth century. At this period, for some unexplained reason, the meaning of the term became uncertain, and with the eighteenth century the term hemeralopia came into frequent use with the ancient signification attached to it of nyctalopia, "night-blindness," whilst the sense of nyctalopia became reversed and came to signify "night-sight." After the eighteenth century, Mr. Tweedy remarks, only a few names can be found to support the original meaning. To those he mentions, however, several might be added, especially John Quincy, who in the tenth edition of his *Lexicon Physico-Medicum*, published in 1787, gives the derivation of the term nyctalopia—from *νύξ*, night, and *ὄψ*, an eye—night-blindness. "Some have said it is those who see by night, others say it is those who cannot see by night; however, it is by the moderns generally understood to signify that disorder in which, as the night approaches, the patient loses his sight and remains blind until the morning, at which time the sight returns and continues all the day." And again, Parr, in his *London Medical Dictionary*, gives nyctalopia (from *νύξ*, night, and *ὄψ*, an eye): "Night-blindness; Imbecillitas oculorum. It is now understood to signify that disorder in which as the night approaches the patient loses his sight and remains blind until the morning." Parr adds, that in Vogel's *System* and in Linnæus' and Vogel's *Genera* the meaning of the terms hemeralopia and nyctalopia were reversed. It is, of course, greatly to be desired that the signification of medical terms should be fixed and invariable; and it is therefore to be hoped that all those who in future use the term Nyctalopia will employ it in the sense which Dr. Greenhill and Mr. Tweedy have with so much industry and acumen shown to be the original and correct sense, and regard it as indicating night-blindness.

#### CASUALTY COINCIDENCES.

It has been often noticed by hospital surgeons that severe, curious, or out-of-the-way accidents seem to occur in groups, and that when one patient is admitted with an unusual injury, a second of a somewhat similar character may be expected shortly to follow. This "fortuitous coincidence" has been illustrated lately at the Middlesex Hospital. About five weeks ago, within ten days, five patients were brought into the hospital who had fallen from houses—three from windows and two from stable-lofts. During the past week two accidents of a similar and unusual kind were admitted within twenty-four hours. On Wednesday evening a lad, aged fourteen, had his foot torn off by machinery; and on the following morning before ten another lad, aged nineteen, was taken to the hospital with his hand lacerated also by machinery in a similar manner. The following is a brief account of the cases: At about seven o'clock in the evening the first boy, aged fourteen, was getting on the stool on which he stood for the purpose of lifting off the papers from the printing-press, when he slipped and was caught by his left foot in the fly-wheel which was in motion, and was carried round by it three times before the machine could be stopped. When admitted it was found that his foot, with the boot, was wrenched from his leg, and was hanging only by the tendons.

The tibia, which was bare of integument for about four inches, was unbroken, but standing away from the foot; the fibula was broken off just above the malleolus. On the following morning another accident very similar to the preceding one was admitted. The lad, aged nineteen, had been cleaning the engine whilst in motion, and was walking away when his foot slipped on some grease, and his right hand slid down the back of the cylinder and was caught at the bottom by the crank, which seized the thumb and tore the ball of it from the palm of the hand, breaking its metacarpal bone and wrenching it away from its articulation with the trapezium. The wrist-joint was laid open, and the integument detached from the palm of the hand. These cases came under the care of Mr. Lawson, who amputated in the one case the leg and in the other the hand. Both cases are doing well.

#### CAVENDISH COLLEGE.

CAVENDISH COLLEGE, named after the Duke of Devonshire, the present Chancellor of the University, who takes great interest in it, and has contributed in various ways to it, was founded in Cambridge, as many of our readers are aware, for the purpose of enabling students to enter the University at a younger age, and to pass through it at less expense than is usually done. It purposed to supply an evident want, for the expenses of a university course prevented many from entering upon it who greatly aspired to it; and the success of the College has justified its institution. A handsome building has been erected, in which the students live under the control and direction of a principal or warden, and they attend the university courses, present themselves for examinations, degrees, &c. The expenses are reduced to a minimum, not amounting to more than £80 or £85, which includes university fees and other educational expenses, as well as board and lodging during the term time, and also during the long vacation. Thus far, however, it appears to have had no distinct university recognition; the students were ranked as non-collegiate students, and were under the superintendence of the board for those students. Now this has been altered by a grace of the Senate, passed on November 9th, for the recognition of Cavendish College as a public hostel of the University. By this the College has been placed upon an independent footing, as an integral factor in the University, and the students are now upon an equality with the students of other colleges, and will no longer be upon the non-collegiate list. We heartily congratulate the College upon this acquisition of an independent position, and wish it the additional success that seems likely to accrue from it. We have often expressed the desire that increased facilities should be given for obtaining the degrees of the old universities. Not that we would lower the estimation in which they are deservedly held. The maintenance of that estimation must depend upon the culture required to obtain them and the tone and character of those who possess them. We are well aware that higher education implies longer time, and therefore greater cost. But this renders it more desirable that the cost should be reduced to the minimum, so as to increase to the utmost the number brought within the beneficial influence of the university course. Let a good standard of education be maintained, and let those who aspire to it come and drink with as little money and at as little price as possible. The increasing number of those intended for the medical profession who are resorting to the University proves the desire in the profession for university education and the status it gives, and is a good indication both for the University and the profession. These students are not generally persons of affluence, and such an institution as Cavendish College cannot but commend itself to them.

## SYNTHESIS OF URIC ACID.

IT is stated that Dr. Horbatschewsky, of the Vienna Chemical Institute, has succeeded in forming uric acid synthetically. As is well known, all attempts to produce this substance artificially have hitherto failed, and considerable doubt has existed with regard to its exact constitution, though it is generally represented as consisting of one radical of tartaric acid and two of urea. From the fact that uric acid under powerful oxidation splits up into molecules of urea, it has been assumed that this body is one of the substances through which every particle of albumen passes before it is thrown out of the body, and on this assumption it has been taught that when oxidation is imperfectly performed there is an accumulation of insoluble uric acid in the blood, which replaces some portion of the urea which ought to be formed. It is upon this view that the doctrine of *lithæmia* has been founded. On the other hand, there are a few who believe that uric acid in the human body in health, and even in disease, is formed in only very minute quantities, and that its pathological importance is to be referred rather to its insolubility than to its excessive production in the system. They hold that though uric acid contains residues of urea, it is not necessarily an antecedent of the latter, and that it is more probable they both start from a body containing at least some of its nitrogen in the form of cyanogen, and that the final cause of divergence lies in the fact that urea is the form best adapted to a fluid, as in the case of mammalia, and uric acid to a solid, excrement, such as is met with in birds and reptiles. This view is strengthened by the increasing evidence we have that the chief antecedents of the uræa in the blood are partly the kreatine, formed in muscle and elsewhere, and partly the leucin and other like bodies formed in the alimentary canal. A writer, who has recently investigated the question from its clinical aspects, remarks that if this view be accepted, uric acid will be regarded as a consequence, and not a cause, of the manifold disorders to which it has been said to give rise; that when it is deposited, the fact of the occurrence of the deposit will have to be referred to the insolubility of the minute quantity that exists in human blood, rather than to any excessive production in the system, and that attention will then be primarily directed to the discovery of the circumstances which lead to the deposit of this insoluble substance, rather than to vague generalisations concerning its over-production from hepatic derangement or gouty proclivities.

## ELECTRO-PYROTECHNY.

IT is asserted, we know not whether "on good authority," that certain theatrical managers contemplate the use of the electric light as a means of producing the semblance of sparkling gems, displayed on the moving persons of fairies, demons, and sprites, in spectacular burlesques or pantomimes to be presented at Christmas-tide. If this be the fact the attention of the Secretary of State should be at once directed to the matter. It is not a question for the Lord Chamberlain, but for the Home Secretary; and we shall hope to hear that an interrogatory has been addressed to Sir William Harcourt in the House of Commons on an early day, bringing the matter under his official cognisance. Great precautions will be necessary to ensure safety. It is not, as everybody who has any practical acquaintance with electric apparatus should be aware, necessary to run the exceptional risk of carrying an accumulator about the person. A very small portable battery, scarcely larger than that contained in the staff now employed for lighting lamps and candles in many private dwellings, would suffice for the purpose of producing the appearance of a brilliant gem. The statement which has been made in one at least of the daily newspapers is, therefore, exaggerated. It cannot, however, be disguised that

there is a danger to be dreaded. The artistic designers of stage spectacles vie with each other in the magnificence of their conceptions, and they are little likely to be content with small effects. If anything of the sort indicated is produced it will be some exceptionally magnificent display of electro-pyrotechny. We shall have thunderbolts hurled from the hand of Jupiter dancing a breakdown, or flashes of lightning played by contortionists and coryphæes; with possibly an electric demon whose diabolic splendour will be dependent on the continuity of some chain which he drags about the stage, and which may "accidentally" entangle some one in the electric circuit. The electric light is at present a pretty toy, and it is probably one that cannot be kept out of the hands of scenic artists, but it should not be allowed to be used without precautions of perfect sufficiency to prevent the accidental discharge of the destructive current in wrong courses. Enough has already been accomplished in the way of killing persons by electricity when that agent has been clumsily or ignorantly employed for legitimate business purposes. It is needless to run the risk of striking the performers in a Christmas pantomime dead by a reckless indulgence in electro-pyrotechny.

## PUERPERAL FEVER AND THE PRACTICE OF MIDWIFERY.

MR. ROWBOTTOM, the borough coroner for Wigan, has just held an inquest on a woman who died from puerperal fever, which had in all probability been conveyed to her by a midwife who attended her in her confinement. The jury were anxious to censure this woman, and also expressed an opinion that it is desirable that midwives should be certificated as competent to follow their calling before being allowed to practise. Since the first week in September from ten to twelve deaths have been registered in the town of Wigan from puerperal diseases, and others have occurred. Eight of these cases have been attended in confinement by this midwife, and it was owing to this fact that Mr. Barnish, the medical officer of health, made known these cases to the coroner. The coroner deemed it his duty to hold an inquiry on the next case that occurred in the practice of this midwife. It was shown, however, at the inquest, that she had ceased to attend any more cases after being warned. Mr. Rowbottom has undoubtedly done good service in calling public attention to this matter by holding an inquest, and this will also have an effect in preventing other women who follow the same calling from spreading such a fatal disease. The midwife in this particular instance could not believe it possible for her to carry infection to those she was attending, although every case she went to succumbed, thus showing how necessary it is that some proof of competency should be shown by this class of persons, who are largely employed by the poor in our manufacturing towns.

## BREACH OF THE MEDICAL ACTS IN LIVERPOOL.

LEWIS GEORGE WYNN has been fined £5 for unlawfully using the title of M.D. He has been committed to take his trial for having signed a vaccination certificate, using the name of Dr. Kennedy. He said it was with Dr. Kennedy's consent. Dr. Kennedy is a graduate of the University of Edinburgh, and said the defendant was a very good vaccinator, and that he (Dr. Kennedy) had never hesitated to sign a certificate of a vaccination that had been done by him. He denied that he had ever authorised him to sign his name. We cannot but regard the practice of signing vaccination certificates for other persons as a very improper one. It is clearly contemplated that a gentleman shall only certify where he himself has vaccinated. To certify cases vaccinated by an unqualified person is to defeat the law.

### RECOVERY OF CHARGES FOR SERVICES RENDERED BY AN UNQUALIFIED ASSISTANT.

WE publish in another column a legal decision delivered by Mr. Commissioner Kerr, in reference to a subject of great importance to practitioners—namely, their right to charge, or their power to recover, for services rendered to patients by their unqualified assistants. Should this decision of Commissioner Kerr's be confirmed, it will entirely invalidate medical charges either in private or public practice for services rendered by an unqualified assistant. Even as it is, it is sufficiently disturbing to practitioners who have employed unqualified assistants in a way that has hitherto been sanctioned by the profession—namely, in strict subordination to and co-operation with themselves. Commissioner Kerr observes, "The law says that a doctor cannot recover for medical advice given by his assistant." The unqualified assistant told his honour that the patient preferred to be attended by him. But this only intensified the dissatisfaction of the judge, who said, "That only makes the case worse. I may tell you that you are liable to be indicted, and perhaps you will be so one of these days if anything goes wrong." Judgment was given for the defendant. This decision seems to us in advance of anything yet delivered by judges; though logically it may be inferred that as a medical man must be registered to recover charges for his own attendance, so his assistant must also be registered for recovering charges for services rendered by him. But if we mistake not, there are decisions to the contrary of this. Mr. Glenn in his "Manual of the Laws affecting Medical Men," says, p. 193, "A registered practitioner may maintain an action for professional services rendered by an unregistered assistant, and it would seem that where such services are performed by a firm of two persons, one of whom is registered and the other not, the firm may recover on a joint claim." (See *Blogg v. Pinker's Ry. and M.*, N.P. 125.) But this and such decisions were prior to the passing of the Medical Act.

### CROUP AND DIPHTHERIA.

PROFESSOR E. HENOCHE draws attention, by means of a paper published in the *Berliner Klinische Wochenschrift* of Oct. 2nd last, to the difference which, according to his view, exists between the non-specific croupous angina and true diphtheria, diseases which he believes are not sufficiently discriminated. At the outset he expresses his conviction that there is such a thing as a non-specific croupous pharyngitis, and he regards croup as only being identical with diphtheria, whether in its pathological or other relations, in the same way as a small-pox pustule resembles a pustule produced by vaccinia or as the result of the inunction of tartar emetic. Any so-called croup having a specific origin is, he alleges, diphtheritic. With a view to the better distinction of the two diseases he points out that the non-specific croupous pharyngitis is generally characterised by the suddenness of the febrile invasion, whereas in diphtheria the fever is at the onset only slight and insidious in its progress. A much less constant difference lies in the fact that in the non-specific disease a single tonsil is, in the first instance, much more frequently affected than is the case in diphtheria. So also the extension of the membrane to the palate, and especially to the back of the pharynx, must always be regarded as highly indicative of true diphtheria, and the implication of the mucous membrane of the nasal passages is a certain sign of that specific disease. On the other hand, certain indications to which importance is at times attached are, according to Professor Henoch, comparatively unimportant. Thus, albuminuria, generally regarded as a symptom of diphtheria, is often absent in undoubted cases of that disease, and micrococci, when dis-

covered by the aid of the microscope, are of little value for the purposes of diagnosis, not only because they are found everywhere in the mucous membrane about the pharynx, but because no definite microphyte has been shown to be associated with diphtheria. The difficulty attaching to a correct diagnosis should, however, in the Professor's opinion, never interfere with measures of prevention, and hence he urges that where there is the least doubt as to which disease is being dealt with, isolation should be rigidly enforced. Professor Henoch proceeds to point out that the disease known as scarlatinal diphtheritis is essentially distinct from specific diphtheria, and, according to his experience, the failure to distinguish between them is largely due to the fact that scarlatina and diphtheria are often treated in the same wards, and that patients, whilst convalescing from the one, contract the other. Cases are cited to show how patients recovering from scarlet fever associated with marked throat lesions have contracted true diphtheria, and it is further shown that in patients who have undergone the operation of tracheotomy for diphtheritic croup, scarlatina with throat ulceration has subsequently intervened, the reception of the scarlet fever being greatly facilitated both in such an instance and in the case of convalescence after extensive diphtheritic throat lesions by the fact of the exposure of a wounded surface to that scarlatina poison. In such instances it is, however, suggested that a correct diagnosis will be aided if it be borne in mind that the throat ulcerations due to scarlatina follow on, and do not precede, the diphtheritic symptoms. In some of these instances the characteristic sequelæ of the two diseases have, in the later stage, been found mingling together, in a manner which might easily be regarded as affording some proof of the unity of the disease, had it not been for the clear distinction between them which was possible at an earlier period of the patient's illness.

### SMALL-POX IN SOUTH AFRICA.

THE presence of small-pox in Cape Town and its vicinity is still exciting great alarm in the minds of the inhabitants of the infected districts, and very energetic efforts are being made to cope with the scourge. The *Port Elizabeth Telegraph*, of the 14th ult., contains a long report of a meeting of the citizens of Uitenhage, presided over by the mayor, at which twelve proposals were agreed to for the protection of the community against the spread of the disease. These proposals included provision for the thorough supervision of houses, the proper supply of lymph, periodical and punctual returns of cases of attack, the regulation of burial of victims to the malady, increase in the public medical staff, and the swearing in of a sufficient number of Europeans and trustworthy natives as special constables to aid in carrying out the law. At Cape Town the deaths from small-pox in the month of September numbered 435. The proportion of vaccinated to unvaccinated in the fatal cases appears not to have been ascertained, but this is a matter which should not be overlooked.

### THE GENERAL INFIRMARY AT LEEDS.

THE authorities of the Leeds Infirmary have decided on increasing the surgical staff of the hospital by the appointment of two assistant-surgeons, on whom will devolve the duty of seeing the surgical out-patients who attend at the institution. We are surprised that a reform which has been required for so many years has been so long delayed, and we would further point out that assistant-physicians are also demanded for the full working of the hospital. The number of medical out-patients is even greater than the surgical, whilst the medical staff is less numerous; and so the authorities must, willingly or unwillingly, soon come to this conclusion. The candidates for the

new appointments include Mr. McGill, who is especially well known as an anatomist and a teacher. He is not only versed in the details of aseptic surgery, but by the introduction of salicylic silk has placed a valuable dressing at the disposal of surgeons who adopt this method. His treatment of an aneurism of the left subclavian artery by temporary compression applied directly to the first part of the vessel attracted much attention at the Medico-Chirurgical Society some six or seven years ago, and marked him out at once as an original thinker as well as a bold operator.

#### ACADEMY OF MEDICINE IN IRELAND.

THE scheme for the amalgamation of the several medical Societies of Dublin has been finally adopted, but will not come into operation until the officers and council are elected, which will take place on the 18th inst. The Academy will commence its meetings this session, and will be composed of fellows, members, and student associates; all the members of the present Societies—the Medical, Surgical, Pathological, and Obstetrical—may join as fellows or members without entrance fee, on payment of the subscription for the current year: two guineas and one guinea respectively. There will be four sections—Medical, Surgical, Obstetrical, and Pathological—and two sub-sections—Anatomy and Physiology, and State Medicine. The sections will be each managed by a president and a council, and the sub-sections by a chairman and a committee. The Academy will also have a president, who will hold office for three years. A meeting of the promoters, consequent on a requisition received by the President of the College of Surgeons, was held last Monday, to consider the question of voting, when a discussion took place on some points of detail which were come to at a previous meeting. An objection was made as to the Surgical section not being sufficiently represented, they having been reduced to ten instead of twenty-one, as in the present Surgical Society. Mr. McDonnell proposed a resolution to the effect that it was inexpedient to make any change in the rules adopted, which was seconded by Dr. Moore, President of the College of Physicians, and finally adopted by a large majority.

#### ACTION OF OXYGENATED WATER ON THE ANIMAL ORGANISM.

COLASANTI and CAPRANICA (*Arch. Italiennes de Biologie*, vol. ii.) have made a series of experiments on dogs with oxygenated water,  $H_2O_2$ , and find that when made to absorb it they experience toxic effects and rapidly die. Toxic doses vary with the size of the animal, 25 c.c. proving fatal to a dog weighing three kilos, or six and a half pounds, and 75 c.c. to a dog weighing thirteen kilos. The intoxication manifests itself on all the functions of the body, but especially on those of the spinal cord. The excito-motor power of this centre is over-excited, the manifestations of which are convulsive phenomena, tetanus, and locomotor ataxy. The physico-chemical phenomena of the tissues are also profoundly modified, for it produces strong glycosuria before death. The disorders of the economy result from the decomposition of the oxygenated water in contact with the living tissues. The phenomena consecutive upon intoxication with oxygenated water are identical with those observed by Paul Bert following the action of compressed oxygen.

#### BANQUET TO THE MEDICAL OFFICERS OF THE EGYPTIAN EXPEDITION.

PREPARATIONS for this banquet, to be held on Tuesday next, at Willis's Rooms, are in a state of forwardness. Sir Garnet Walseley has accepted the invitation to be present, and other distinguished guests are expected.

#### ARBITRARY REDUCTION OF SALARIES OF UNION OFFICERS IN BALLYMENA.

THE guardians of the Ballymena Union have determined on serious, and almost wholesale, reduction of the salaries of the medical officers of the Union. One happy gentleman, Dr. Ross, is excepted, on the ground that he was exceedingly attentive to his duties, and had held his appointment for a long time. The midwife, too, escapes. But the *Ballymena Observer* gives the following account of the fate of others:—"The salaries of Dr. Dysart, Portglenone; Dr. M'Kay, Clough; Dr. Chestnut, Ahoghill; Dr. Hays, Glenwherry; Dr. Courtenay, Galgorm; Dr. Picken, Toome; and Dr. Dickson, Broughshane, were reduced from £90 to £87 10s. each, while the salary of Dr. Gilmore (apothecary, Ballymena Dispensary) was reduced from £52 to £42. The matter with reference to the salaries of the relieving officers was postponed in the meantime." A proper motion to take the opinion of the Local Government Board on the question was rejected by a majority of two, and with some very discreditable and disrespectful allusions to the Local Government Board. We trust, nevertheless, that the minority will bring this matter under the notice of the Local Government Board, and secure justice to a class of men who cannot be injured without hardship to the poor whom they serve, and serve well.

#### "FLOGGING IN BOARD SCHOOLS."

WE have not a word to say against the use of the "birch" applied to the proper part of the person, and moderately and wisely used as a punishment for the graver offences of children, such as lying, dishonesty, wilful disobedience, and the like offences; but caning children on the hands and for trivial acts of wrong-doing is not to be tolerated; and we doubt very much whether the masters of Board schools should be entrusted with the power of chastising the poor little urchins who are placed in their power. However that may be, it is a scandal that schools under the *ægis* of the Board should be allowed to be so conducted that the fear of "flogging" keeps children away from them. The idea of two teachers holding a little boy down on a desk while the master canes him, as is the alleged manner of procedure at some of these schools, is irritating, and stirs the mind with a vehement wish to have the opportunity of serving the officials—who, dressed in a little brief authority, so abuse it—as they serve their pupils.

#### THE WAYNFLETE PROFESSORSHIP OF PHYSIOLOGY.

A STATEMENT appeared last week in a contemporary to the effect that Dr. Burdon Sanderson had been induced to become an opponent of Dr. Gamgee in his candidature for the new Chair of Physiology. We have reason to believe that this is a mistake. Dr. Burdon Sanderson has, no doubt, been spoken of as a possible occupant of the chair, but he has made no application to the electors, and we understand that he has received no suggestion from any of them that he should become a candidate.

#### HEALTH OF VENTNOR.

A DECIDED contradiction is given to the statement that typhoid is prevalent in Ventnor. According to Dr. Woodford, the medical officer of health, there were only three cases of typhoid in 1881, and there have been only three under treatment this year. Of these, Dr. Woodford says, two were imported. All recovered. Five of the chief practitioners in Ventnor, in a letter dated November 2nd, aver that there is not a single case of typhoid under treatment at the present time in the town.

### THE NORWICH VACCINATION INQUIRY.

At the moment of going to press, we have received a copy of the official reports on the Norwich Vaccination Inquiry. It is impossible in this issue to do more than make brief reference to them. But a hasty glance at the reports is sufficient to cause a feeling of surprise in the mind of the reader. There is a complete absence of that thoroughness of investigation necessary for the solution of the problem which it was the inspector's duty to study. Conclusions have been come to for which there would probably be little foundation if the facts had been duly investigated and considered. It is this circumstance which we suppose has led to the publication of a memorandum addressed by Dr. Buchanan, F.R.S., the Medical Officer, to the President of the Local Government Board, showing that the conclusions which have been arrived at by the inspectors are certainly not borne out by the evidence, and that many important considerations which might have led to an elucidation of the use of erysipelas have been overlooked.

### BOTANY AND COMPARATIVE ANATOMY AT CAMBRIDGE.

THE Board of Medical Studies at Cambridge has just presented to the Vice-Chancellor its report, recommending that attendance on lectures on Botany and Comparative Anatomy be no longer compulsory on medical students, although the examination in those subjects will be continued. The recommendations have not yet actually been adopted by the University. It is argued that if attendance on lectures on Botany and Comparative Anatomy be no longer enforced, these subjects will then, in this respect, be placed upon the same footing as Physics. There is, at present, no requirement compelling medical students to attend a course of lectures on Physics; and this arrangement is, it is stated, found to work satisfactorily.

### CONCEALMENT OF BIRTH.

THE case of Charlotte England, on which we lately commented, terminated curiously. She was found guilty, but strongly recommended to mercy. The child, it may be remembered, was found between two beds in a piece of calico, and the surgeon, Mr. Ford, believed it had been born alive. She had previously borne a good character, and it was intimated that if she was allowed her freedom the father of the child would marry her. This prevailed with judge and jury, and she was dismissed, bound over in her own recognisances in £20 to good conduct. Decisions of this sort are very kind to mothers under such circumstances, but very hard upon babies, and certainly do not tend to check the practice of infanticide.

### SIR THOMAS WATSON, BART.

THE state of this revered physician has during the past week been one of increasing weakness, and, we regret to state, of increased suffering. Indeed, so distressing is his present condition that those to whom the loss of so great and good a man will cause the most acute pain, can but hope and pray for his speedy release.

### MEDICAL ADVERTISING IN THE LAY PRESS.

THE Royal College of Physicians of Ireland is to be congratulated on the decided tone of its resolution condemning the practice of advertising medical works in the lay press. It will be remembered that the London College a few months since passed a resolution which limited censure to the practice of "extensively" advertising, whilst the question of advertising in the lay press was left altogether to the

conscience of the Fellows. The Irish College has, however, spoken with no uncertain sound on this important matter, by declaring that the advertisement, by any of its Licentiates, Members, or Fellows, of "medical works in other than medical publications" is censurable by the College.

### MR. ANTHONY TROLLOPE.

MR. ANTHONY TROLLOPE is suffering from aphasia, with some loss of power of the right side. He has never at any time been unconscious, and there has been nothing of the nature of a fit. His intellect remains unimpaired, and he is perfectly cognisant of everything that is being done for him. The attacks of shortness of breath, from which he has recently suffered, distress him from time to time, but he continues to progress favourably. Dr. Murrell visits him daily, and Sir William Jenner has seen him twice in consultation.

THE annual course of five lectures, free to the public (as required by the will of Mr. Brown), will be delivered by the Professor-Superintendent of the Brown Institution (Dr. C. S. Roy), in the theatre of the University of London, on the afternoons of the 20th, 22nd, 24th, 27th, and 29th of the present month, commencing each day at half-past five o'clock. Subject: "On the Experimental Pathology of the Heart."

DR. ARTHUR VERNON MACAN has been elected to the post of Master of the Rotundo Lying-in Hospital, Dublin, in the vacancy caused by the retirement of Dr. Lonbe Athill. There was little interest connected with the appointment, as it was a foregone conclusion that Dr. Macan would be elected.

THE Sandbach Local Board have been threatened with dissolution by the Central Board for inattention to the request of the latter Board for information with respect to the sewage-disposal of the town, also for delay in taking steps towards providing a proper water-supply.

IN the report presented by the General Purposes Committee to the Brighton Town Council last week, the expenses connected with Dr. Richardson's inquiry were stated to be £535, whilst those arising from the investigation of Sir J. Bazalgette amounted to £224.

AT the College of Physicians in Ireland an election for an examiner in sanitary law and in sanitary engineering, to examine candidates for the certificate in Sanitary Science for the ensuing year, will take place on December 1st.

PERHAPS it may be well to remind intending competitors that the essays for the Triennial and Jacksonian Prizes of the College of Surgeons must be sent in on or before Saturday, the 30th prox., addressed to the Secretary of the College.

DR. SEDGWICK SAUNDERS, medical officer of health for the City of London, reports for the week ending the 4th inst. a death-rate of 8.11 per 1000—a rate lower, he believes, than any yet recorded for the same area.

THE guardians of St. Saviour's Union have agreed to pay 1s. a day for a pauper patient sent to Guy's Hospital for treatment, the case being one of ophthalmia.

THE Treasurer of the Lincoln Lunatic Hospital has received a legacy of £200, under the will of the late Mr. William Keep, for the benefit of the institution.

## THE MINUTES OF EVIDENCE BEFORE THE ROYAL COMMISSION ON MEDICAL ACTS.

### II.—THE INEFFICIENCY OF THE MEDICAL COUNCIL.

*Examination of Sir JAMES PAGET, Bart., F.R.S.*

246. (*Lord Camperdown.*) Can you suggest any better central body than the present Medical Council?—No.

247. Then the chief function of the Medical Council in connexion with the questions of study and examination would apparently consist, in your opinion, in supervising and reporting upon these matters?—Yes.

248. And not in exercising any direct authority?—I would have them exercise no direct authority. They should have power to check manifest and grave wrongs, but not to interfere in any manner in matters of detail.

249. Would you kindly give us your reasons?—I think that all these questions of detail are managed best by those who are nearest both in time and local relations to the teachers and the schools. The conduct of the schools must in great part be determined by the examiners; the conduct of the examiners must in great part be determined by what is possible in the schools; and therefore the relation between examiners and schools cannot to my mind be too close. Then next above the examiners are the several licensing authorities, whether separately or in conjoint boards; and they would be much nearer to the office of teaching and examining than the Medical Council can be. The Medical Council of necessity consists for the most part of seniors and persons who, I dare say with great justice, are elected to that high dignity; but they are not for the most part such as have lately been engaged in practice or in examining, and are not completely familiar with the progress of science at the present time, or with the manners of teaching in the schools.

253. With regard to the present constitution of the Medical Council you are aware, no doubt, that there has been a considerable demand for direct representation from a certain portion of the profession, or at all events from certain persons who profess to represent the working profession?—Yes.

254. You, I believe, gave your opinion on the subject on a former occasion?—Yes.

255. Would you mind repeating it shortly?—It seems to me to be just one of those cases in which public feeling should be satisfied. It seems to be deemed desirable by the public feeling that the profession should be represented on the Medical Council. I think it will make no difference, whatever in the manner or the quantity of work done by the Council, and for the satisfaction of the feeling I think it should be granted. I have no other motive for thinking so.

256. I think you have already said that the addition of a few members to the Council, or the taking away of half a dozen members, would make, in your opinion, very little difference in the working qualities of the Council?—Very little difference.

257. You have no doubt considered the relative share of the representation on the Medical Council which belongs to different individual bodies. Do you consider that there ought to be any change in any instance?—No, I have no clear opinion on the matter. It seems to me, as often as I have thought of it, to be in the same condition of apparent inconsistency as I am told the constitution of the House of Commons is, where the 4,000,000 of London are represented by only the same number of members as might be found in some small set of boroughs in the country.

258. In the House of Commons they are talking of redistribution schemes; would anything of that kind in this case be desirable?—I think it might be, as soon as the House of Commons has made a satisfactory redistribution.

387. Would you give the Medical Council any power of saying that the schemes adopted by the several conjoint bodies were reasonably uniform as to value?—Yes, reasonably uniform.

388. I mean not fixedly uniform?—Yes, reasonably uniform, and that the standards were so too.

488. (*Mr. Simon.*) Am I right in thinking that your view of the organisation to be desired would be something to this effect, that in each division of the United Kingdom there should be a Board constituted of the existing authorities?—Yes.

489. Those authorities to be placed under the supervision of a General Council?—Yes.

490. That, General Council having for its functions to make broad regulations upon matters of education?—Very broad ones.

491. To see to the reasonable uniformity of qualifications as between the three divisions of the United Kingdom?—Yes.

492. And in relation to all three divisions, so far as might be necessary, to keep up as high a standard as the circumstances of the time would allow of medical education?—If it is meant that it should be left to the Medical Council to raise the standard, I do not agree to it. I should leave that to the several bodies and the Medical Council should approve; but I should not regard the Medical Council as the best judge of either the time, or the method, or the degree of raising it.

493. You mean that if there was a difference between the standard of one division and another the General Council would form its opinion whether the lower of the two was too low?—Yes.

494. And would act accordingly?—Yes.

495. And would in that sense act in the maintenance of a higher standard?—Yes. As I understand the question, it is, would you grant more power to the Medical Council—that is, should the Medical Council have more power to compel. I do not think it should have that.

496. I was speaking of the tendency of what its influence should be. It is the body to which one would look to see influence in favour of the higher standard where there was difference between the divisions as to their particular standards?—Yes.

497. And you would look to the divisional boards constituted out of existing authorities to regulate the details of education?—Yes.

498. And to appoint directly or indirectly the examiners for this purpose?—Yes.

499. And it was that sort of plan, as a voluntary plan, that you would have in England by the action of the Committee of Reference of which you were chairman?—Yes.

500. But you think it would be a good thing that a similar arrangement should be adopted in each division of the kingdom. I do not mean similar in details, but similar in principle?—Similar in general principle.

*Examination of Prof. PAGET, M.D., F.R.S., of Cambridge.*

883. (*Chairman.*) Now, let me ask you a question with regard to the number of the Medical Council. Do you think that it would be possible to reduce the present number of the Medical Council?—It would not, I think, be right or wise to reduce it as things are at present. In the first place there are six nominees of the Government. I think my experience of those gentlemen, while I was for eleven years a member of the Medical Council, was that they were very efficient men, indeed; their voice was a very useful one in the Medical Council. I think any reduction in their number would be an alteration for the worse. Then the others (with the exception of the President) are representatives of the different licensing bodies. Now, under the Act of 1858, the doings of any one of those bodies are liable to be discussed by the Medical Council publicly, and they are even liable to be brought up before the Privy Council. These bodies are, all of them, subject to a certain amount of control by the Medical Council. The Council has a controlling power over their proceedings with reference to medical diplomas and degrees. I think that is an abundant reason why these bodies have a right to be represented on the Medical Council. Being in a certain sense governed by the Medical Council, they have a right to be represented in it. Of course, in the case of a conjoint board, that state of things might be altered. Besides that, there is another very good reason for it, the chief business of the Medical Council being to deal with medical education and medical examinations, I think those nineteen bodies are the very bodies of the whole country fittest to select persons suitable for the purpose.

884. Would you be disposed to make any change in the representation of the various bodies on the Medical Council?—There they are. If I had been consulted before 1858 I should have made one or two little differences. I think it is not quite fair that the University of Edinburgh should be linked with Aberdeen. I think the University of Edinburgh should have been linked, certainly, with St. Andrews, which has not anything like the same claim to being individually represented.

5. You are aware of the cry which has arisen for direct representation of the general profession in the Medical Council?—Yes.

3. Would you give us your opinion upon that point?—My opinion is, that persons elected in the way which has been proposed would not add to the efficiency of the Medical Council for its principal duty—namely, that of controlling and directing medical education and medical examinations; before I do not think it is for the interest of the public to have persons elected in that way, but (I think there is a great deal to it) I think persons elected in that way would more than the present members represent the interests of the mass of the medical profession, and now and then subjects have been brought before the Medical Council which have been subjects not of medical education generally, or at all, but subjects relating to measures affecting the interests of the medical profession. If the questions be brought before the Medical Council, then, I think, there is some ground for a claim on the part of the profession to be more directly represented.

In the year 1878, I think, the Government requested the opinion of the Medical Council on two points; one was the propriety of admitting women on the Medical Register, and the other was the admission of colonial and foreign graduates to the register on different terms to those on which British graduates are admitted. Both those were questions affecting the interests of the mass of the profession at large; and I think if such questions be discussed by the Medical Council the mass of the profession have some claim to be directly represented in it. The only other thing I have to say about it is that I think this question is of far less importance than it has been made either one way or the other. I would add one single word, if it were determined that such persons should be elected, I think the inconvenience and turmoil of those general elections should be minimised. It has been proposed that those members should be elected for five years. I would suggest, if that were the case, that imposing one of those members should resign, or become incapacitated, or die, that that single vacancy should not be filled up by another general election, but that the vacancy could be filled up by the Government, or in some other less troublesome way than by a general election, so that the profession might not be disturbed by those elections more frequently than necessary. I see that a Bill, which is now before Parliament, and which was, I think, brought in by Mr. Hardcastle (it is dated 1881), proposes a Medical Council consisting of twenty-six members, appointing six by direct representation, and leaving out of representation the Faculty of Glasgow, the Apothecaries' Society of London, and the Apothecaries' Hall of Dublin. I think if a Medical Council were established in the mode proposed in that Bill then such vacancies as might occur in the way I have mentioned, that is accidental vacancies, might with propriety be filled up in each division of the kingdom by those bodies which are left out of representation.

857. Do you wish to add anything to your evidence on the licensing question?—No, I think not; I do not remember anything.

Professor HUMPHRY.

The following suggestions were handed in by Professor Humphry in reference to the

#### Medical Council.

*Functions.*—Not to be regarded as representing certain bodies, but as acting in the interests of the public, with the view that the qualifications of those entering the profession may be sufficiently high, but not so high as to lead to undue diminution of the numbers.

To receive and consider education and examination rules from the conjoint board. In case of non-approval, to confer with the board. If necessary, to make representation to the Privy Council.

To adjust differences between the combining authorities on the board, and between the latter and the medical schools, with appeal to the Privy Council.

To make suggestions to the board respecting education and examination.

To visit examinations conducted under the board and under the medical authorities.

To see that the examinations and rules, and fees, in the three divisions of the kingdom are nearly equal.

To prepare and publish the Pharmacopœia.

To keep and publish the Medical Register, and to strike off names from it as at present.

To report annually to the Privy Council their proceedings, statements respecting education and examination, a financial statement, &c.:

#### Constitution:—

6	to be appointed by Crown as at present.
2	" " by Conjoint Board for England. <sup>1</sup>
1	" " " " " " Scotland. <sup>1</sup>
1	" " " " " " Ireland. <sup>1</sup>
2	" " " " " " by whole profession in England.
1	" " " " " " Scotland.
1	" " " " " " Ireland.
14	

Members of the board not to be members of the Council unless appointed as such by the board.

Appointment of four members by the profession a concession to wishes of profession, not as being a good mode of appointment.

Appointment of four members by conjoint boards, for the purpose of maintaining good relations between the board and the Council.

Present Medical Council has worked as well as councils usually do, as well as could be expected, seeing that it is composed of members, busy men, from the three divisions, and had to harmonise the views and interests and customs of the three divisions. Its influence has been considerable. The representation of several authorities by its members has facilitated improvements. Visitation of examinations has been beneficial, but it needed to be supplemented by visitation of schools.

Absolute authority should not be vested in the Council, however composed. Better that one body (the board) should make rules for education and examination, and conduct the examinations; and that another body (the Council) should consider and report upon these rules to the Privy Council. The intervention of the Privy Council would be rarely necessary.

The number of medical authorities might with advantage be reduced.

Foreign and colonial practitioners should be required to pass the practical and clinical parts of the Board examination, in the same manner as those who have passed the examinations at the British universities.

#### Examination of Dr. JACOB, of Dublin.

Dr. Jacob said (examined by the *Chairman*) the subject of direct representation had been repeatedly discussed in the last six or seven years by the Irish Medical Association, and as often the Association had petitioned Parliament in favour of this change.

1352. Speaking from your own knowledge, do you believe that the general body of practitioners really attach great value to direct representation?—I do decidedly.

1353. Is that because they regard the Medical Council as charged with the duties of supervising general study and examination, or is it because they regard it as a sort of medical parliament at which general questions affecting the medical profession would be entertained?—The feeling of the profession in Ireland, so far as I understand it, is that the General Medical Council has not been successful in the purpose for which it has been established by reason of its misconstitution; part of its misconstitution being the omission to represent the medical practitioner, and the representation of the licensing bodies being altogether excessive and redundant.

1354. In what way has the Council failed, in your opinion, to represent the medical practitioner in Ireland?—In the subjects in which the general working practitioner is daily interested. For instance, the practice of the profession by unlicensed persons has not been dealt with by the General Medical Council at all; on the contrary, the Council has definitely declined to enter upon any course of checking unlicensed practice whatsoever; and the result of that is that, both in Ireland and elsewhere, the practice of the profession by unqualified persons has gone on unchecked, and has achieved great proportions. The feeling of the profession, also, is that even if this function were not neglected by the General Medical Council, the presence of direct representatives in the Council is necessary to counterbalance the

<sup>1</sup> Professor Humphry proposes to leave out of the Conjoint Boards for England, Scotland, and Ireland, respectively, the Apothecaries' Societies of England and Ireland and the Faculty of Physicians and Surgeons of Glasgow.

excessive influence of the licensing corporations in that body.

1355. Do you consider that Parliament in passing the Act of 1858 intended that the Medical Council should deal with this question of unqualified persons practising?—I am strongly of that opinion.

1356. In your opinion, did the Act of 1858 give to the Medical Council the power of dealing with that question?—Certainly. I think they possess that power.

1357. Would you point out to me what clause gave them that power?—I think they have power under the 40th section of the Act of 1858. That section says: "Any person who shall wilfully and falsely pretend to be, or take, or use the name or title of a physician, doctor of medicine, licentiate in medicine and surgery, bachelor of medicine, surgeon, general practitioner, or apothecary, or any name, title, addition, or description implying that he is registered under this Act, or that he is recognised by law as a physician, or surgeon, or licentiate in medicine and surgery, or a practitioner in medicine or an apothecary, shall, upon a summary conviction for any such offence, pay a sum not exceeding twenty pounds."

1358. You see the important part of it is, "or any name, title, addition, or description implying that he is registered under this Act?"—Yes. No effort whatsoever has ever been made by the General Medical Council, so far as I know, to enforce these penalties against persons practising without qualification.

1359. Where does the Act say that the Medical Council is to enforce these penalties?—The Act does not put it upon the Medical Council to do so. But I consider that inferentially it is the duty of the General Medical Council to carry into effect the objects for which the Medical Act was constructed, and that the suppression of illicit practice was one of those objects which has not been carried into effect.

1360. Then Parliament has not imposed that duty upon the Medical Council, I understand?—It is not stated in the Medical Act that the Medical Council is charged with that duty; but the Council is charged generally with the administration of all the purposes of that Medical Act, this being one of those purposes.

1406. (*Master of the Rolls.*) Although I have not been here from the commencement of your examination, I understand that you are in favour of direct representation, as it is called, on the Medical Council?—I am.

1407. Do I understand that you wish the functions of the Medical Council to remain as they are, or to be extended?—I think that the powers which the Medical Council now possess might be made more definite and more explicit; but I think it possesses most of the powers—in fact, I would say all the powers—necessary, if they were made more explicit and definite.

1408. Do you think that those powers could be more usefully exercised, without the attendance of the public press at their debates?—No, I think they would be much less usefully exercised in that way.

1409. Have you directed your attention to the proportionate representation which you would like? I do not understand that you wish all the members of the Council to be elected by direct representation?—Certainly not.

1410. What proportion would you say?—The method of reconstruction which, if I were asked my opinion, I would suggest would be, firstly, that the Medical Council, as it at present stands, should be materially reduced in number; first, by disfranchising certain bodies which seem to me not to have a right to appear on the General Medical Council, and, secondly, by coalescing together other medical bodies whose functions are somewhat analogous, and whose share in licensing is not very large. And having so reduced the numbers, I would then add six direct representatives.

1411. And how would you elect those six; would you have separate ones for England, Ireland, and Scotland?—Yes.

1412. I suppose they would be divided in some way between the three divisions of the kingdom?—The branch registers of each of the three parts of the kingdom would supply the means of division.

1413. Then each of the divisions of the kingdom would elect one or more members of the Council; how do you propose to elect them?—In the same way as ballot elections are generally held, by sending round a voting paper at a given

date; certain members being nominated, and their names contained upon this voting paper, let the vote be given. This voting paper being sent round from the Branch Medical Council to all the practitioners appearing on the register of that Council at their registered addresses, and having been filled up, would be returned duly signed; and then the votes should be totted up. This election I would propose to be held every three or five years.

1414. You think that that would be a sufficient guarantee; that it is not very likely that people would take the trouble to commit fraud in such an election?—No, I believe not. Besides, I believe that arrangements, which would get rid of any chance of fraud, are quite capable of being made for voting by paper. In the case of synod elections in the Irish Church they are largely held now by paper votes, and there is a machinery by which it can be done without any danger of fraud. My calculation is that this would cost about £200 to the General Medical Council every three or five years, and my opinion is that that £200 would be amply repaid to the Council by the corrections in the Medical Register which the election circulars would bring home to them. The Medical Register now is an inaccurate document, from the fact that a man once placed upon the register cannot be removed from it except under the Act of Parliament, and by compliance with certain clauses of the Act of Parliament; and if he dies without the knowledge of the registrar, or removes from one place to another, or retires from practice without giving notice, as happens in many instances, his name then still appears. Therefore, I take it, the expense incurred in this matter need not be considered, as the thing itself would yield a return irrespective of the elective return.

1594. (*By Mr. Cogan.*) Which do you think should be disfranchised and which coalesced?—I am strongly of opinion that the Apothecaries' Company, both in Dublin and London, should cease to send representatives, and I think that the Glasgow Faculty has ceased probably to have a claim. Those are the three bodies which I would name as open to disfranchisement, and as to coalescence, I should think that the University of Durham might advantageously be conjoined with some other body in returning a representative. I do not like to individualise, but I am quite clear with reference to those that I have named.

## VITAL STATISTICS.

### HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 6058 births and 3522 deaths were registered during the week ending the 11th inst. The annual death-rate in these towns, which had been equal to 21.4 and 21.3 per 1000 in the two preceding weeks rose to 21.7 last week. The lowest death-rates in these towns last week were 12.9 in Brighton, 15.6 in Wolverhampton, 15.7 in Leicester, and 16.5 in Norwich. The rates in the other towns ranged upwards to 28.2 in Liverpool, 28.3 in Cardiff, 28.4 in Manchester, and 32.4 in Sunderland. The deaths referred to the principal zymotic diseases in the twenty-eight towns were 468, showing a further decline from recent weekly numbers; 131 resulted from scarlet fever, 101 from measles, 98 from "fever" (principally enteric), 59 from diarrhoea, 46 from whooping-cough, 27 from diphtheria, and 6 from small-pox. The lowest death-rates from these zymotic diseases were recorded in Plymouth and Leicester, and the highest in Sunderland and Cardiff. Scarlet fever showed the largest proportional fatality in Sunderland and Cardiff. No fewer than 19 of the 27 deaths from diphtheria in the twenty-eight towns were recorded in London. Small-pox caused 4 deaths in London, and 1 both in Wolverhampton and in Newcastle-upon-Tyne. The number of small-pox patients in the metropolitan asylum hospitals, which had declined in the three preceding weeks, from 84 to 70, were again 70 on Saturday last; 13 new cases of small-pox were admitted to these hospitals during the week, against 8 and 7 in the two previous weeks. The deaths referred to diseases of the respiratory organs in London, which had been 355 and 347 in the two preceding weeks, further declined to 330 last week, and were 126 below the corrected weekly average. The causes of 114, or 3.3 per cent., of the deaths in the twenty-eight towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Plymouth, Derby,

Huddersfield. The proportions of uncertified deaths largest in Oldham, Halifax, Hull, Sunderland, and Castle-upon-Tyne.

#### HEALTH OF SCOTCH TOWNS.

The annual death-rate in the eight Scotch towns, which the four preceding weeks had steadily increased from 24.3, declined again to 22.0 in the week ending the 11th; this rate exceeded by but 0.3 the rate that prevailed in the twenty-eight English towns. The deaths referred to the principal zymotic diseases in these Scotch towns, which had declined in the six preceding weeks from 117 to 85, were 89 last week, and equal to an annual rate of 3.8 per 1000. The deaths from diphtheria in the Scotch towns, which had been 16, 19, and 24 in the three previous weeks, further rose to 25 last week, of which 6 occurred in Glasgow, 5 in Dundee, 5 in Aberdeen, and 4 in Edinburgh. The 21 deaths from diarrhoea, including 8 in Glasgow, were one above the number in the previous week. The 15 fatal cases of whooping-cough, however, showed decline from the increasing numbers in recent weeks; 5 are returned both in Glasgow and Dundee. Of the 12 deaths from measles, 8 occurred in Dundee and 4 in Glasgow. The deaths referred to "fever," which had been 12 and 6 in the two previous weeks, rose again to 11 last week, of which 6 occurred in Glasgow. Four of the 5 deaths from scarlet fever were also returned in Glasgow. The deaths referred to acute diseases of the lungs in the eight towns, which had increased from 100 to 135 in the four preceding weeks, were 130 last week, and 2 above the number in the corresponding week of last year. The causes of 88, or 17 per cent., of the deaths in the eight towns last week were not certified.

#### HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 22.5 and 20.4 per 1000 in the two preceding weeks, rose to 27.7 in the week ending the 11th inst., and exceeded that which prevailed in any week since the middle of May last. During the first six weeks of the current quarter the death-rate in the city averaged 22.9, against 19.9 in London and 18.3 in Edinburgh. The 185 deaths in Dublin last week showed an increase of 51 upon the number returned in the previous week. The deaths from the principal zymotic diseases, which had been 8, 13, and 14 in the three previous weeks, were again 14 last week; they were equal to an annual rate of 2.1 per 1000. The deaths from "fever," which had been 5 and 7 in the two previous weeks, rose to 8 last week, and exceeded the number in any week since the beginning of September. The fatal case of diphtheria was the first recorded within the city since the end of September. The deaths both of infants and elderly persons showed a considerable increase upon the numbers returned in recent weeks.

#### THE SERVICES.

Brigade Surgeon W. R. Oliver, A.M.D., has received orders to join at Colchester for duty in the Eastern District.

Surgeon-Major W. D. Wilson, A.M.D., has received orders to hold himself in readiness to return to Egypt for duty.

ARMY MEDICAL DEPARTMENT.—Brigade Surgeon George Langford Hinde has retired on temporary half pay; Brigade Surgeon-Nicholas Ffolliott has been granted retired pay, with the honorary rank of Deputy Surgeon-General; Surgeon-Major William Fuller Bennett, M.D., has been placed upon temporary half pay on account of ill health.

ADMIRALTY.—To be Hon. Surgeon to Her Majesty: James Jenkins, Esq., C.B., M.D., retired Inspector-General of Hospitals and Fleets, vice Dr. Johnston, deceased. Deputy Inspector-General of Hospitals and Fleets Samuel S. D. Wells has been promoted to the rank of Inspector-General of Hospitals and Fleets, in Her Majesty's Fleet, with seniority of Nov. 10th.

The following appointments have been made:—Fleet-Surgeon Charles H. Slaughter, to the *Northampton*; Surgeon Anthony R. Lynch, to Sheerness Dockyard, vice Breton; Fleet Surgeon James Thomson, to Chatham Dockyard, vice Charles H. Slaughter.

## Correspondence.

"Andi alteram partem."

### THE DISCOVERY OF TRICHINA SPIRALIS.

To the Editor of THE LANCET.

SIR,—In the lately issued edition of "Quain's Dictionary of Medicine" I found, under article *Trichina*, the following: "A genus of nematoid worms originally established by Professor Owen for the reception of the minute spiral flesh-worm (*T. spiralis*). This entozoon was first discovered by Sir James Paget when a student at Bartholomew's Hospital."

As in the paper<sup>1</sup> originally establishing the genus and species I detailed the series of microscopical observations supporting such conclusion, made in the conviction of their originality, and that the knowledge so gained was acquired prior to any other information on the subject, the statement by Dr. Cobbold, the writer of the article above quoted, may lead to the inference that my zoological conclusions were based upon facts due to another and prior observer, and may render me liable to the suspicion of having done injustice to Sir James Paget.

I still retain the letter accompanying the portions of muscle of the subject received in the dissecting-room, transmitted to me by Mr. Thomas Wormald, then (Feb. 3rd, 1835) Demonstrator of Anatomy at St. Bartholomew's Hospital. It is as follows:—

"Dear Owen,—I send you some sort of organised being, as I believe, which occupies the muscles of a subject under dissection at St. B. H., and, as I know you are a keen hand for parasitical things, from 'crabs' downwards, I send the enclosed for your inspection.—Ever yours sincerely,

(Signed) "THOS. WORMALD."

The honest, downright character of my correspondent is a fixture in the memories of all who knew him. Had the discovery of the nature of the "organised being" been made at the date of that letter by any student or officer in the anatomical school, it would have spread through the dissecting-room, and it is inconceivable that Wormald would have failed to mention the fact.

No other notice or information whatever had reached me of this case with its peculiar muscular condition. On the day after receiving the letter and specimen I replied by informing my friend that the calcareous specks were cysts enclosing one or more microscopic worms, the nature of which I should shortly publish. My worthy correspondent died in the conviction of my rightful claim as discoverer of *Trichina spiralis*, as I was assured by his son, Mr. P. H. Wormald, shortly after his father's decease. The only student at St. Bartholomew's, at that time an expert in microscopical research, was Arthur Farre (now M.D., F.R.S.), who communicated an acceptable addition to the anatomy of *Trichina spiralis* to the *London Medical Gazette*, December, 1835, under the conviction, common to the medical school, of my independent relation to the species as its discoverer.

It was not until I had completed my researches and drawings that I learnt that Mr. Paget had taken portions of the muscles of the same subject to the botanical department of the British Museum, where the microscope of Robert Brown had enabled him to recognise the wormlet in the cyst, and this I did not fail to state in the paper above cited.

I am, Sir, your obedient servant,

RICHARD OWEN.

Sheen Lodge, Richmond Park, Nov. 14th, 1892.

### A NEW AND VERY DELICATE TEST FOR GRAPE SUGAR.

To the Editor of THE LANCET.

SIR,—While using picric acid as a test for albumen in the urine, I have, as it were by a happy accident, come upon what I believe to be an extremely sensitive test for grape sugar, whether in the urine or elsewhere. The history is briefly this:—Amongst my morning patients on Tuesday, Nov. 14th, there were two whose urine, as I knew from

<sup>1</sup> Transactions of the Zoological Society, Feb. 1835, p. 315, Pl. xii.

previous examination, contained albumen and a trace of sugar. To the first specimen I applied what is known as Moore's test for sugar—i.e., boiling with an equal bulk of liquor potassæ. The quantity of sugar being small, the brown colouration was very slight, and it occurred to me to add a small quantity of a saturated solution of picric acid to the boiling mixture, when in an instant the liquid assumed a deep purple, almost black, colour. I tried the same experiment on the second specimen of slightly saccharine urine with the same result. When equal volumes of liquor potassæ and a saturated solution of picric acid are mixed, there is usually a precipitate of picrate of potash; on boiling the mixture the precipitate is dissolved, and forms a transparent orange-red liquid. On adding a small quantity of saccharine urine to this liquid and continuing the application of heat the colour is rapidly deepened. The deepening of colour produced by the action of sugar is rendered more striking when the liquor potassæ is only slightly tinged yellow by a small amount of picric acid. It would seem that the effect of the picric acid is to intensify the reaction between the caustic potash and the sugar.

Having obtained this result, I added to the boiling mixture of liquor potassæ and solution of picric acid a drop or two of diluted grape juice, with the same intense deepening of the colour.

With a solution of cane sugar no change of colour occurred; but when the cane sugar had been converted into grape sugar by boiling with hydrochloric acid, the addition of a very few drops of the solution to the boiling mixture of liquor potassæ and picric acid solution caused immediately the same intense deepening of the colour as occurred with the addition of the saccharine urine.

As a result of these few but decisive experiments, I venture to say that by boiling this strongly alkaline solution of picrate of potash with a liquid suspected to be saccharine, we have a test for grape sugar far exceeding in delicacy the liquor potassæ test, or indeed, any other known test for that substance. It appears that the effect of the picric acid is to increase to an extraordinary degree the delicacy of Moore's well-known test for glucose.

I have ascertained that a solution of crystallised picrate of potash boiled with a solution of grape sugar causes no change of colour; the presence of caustic potash in excess is essential for the development of the reaction. I have also ascertained that 1·5 parts by weight of grape sugar dissolved in 10,000 parts of distilled water may readily be detected by this extremely delicate colour test. It is probable that the true limit of delicacy of the test exceeds this rather rough estimate, but I have given directions for more accurate determinations to be made, the results of which I hope soon to communicate.

I am, Sir, yours faithfully,

Savile-row, W., Nov. 15th, 1882.

GEORGE JOHNSON.

## SHOULD DISEASES OF CHILDREN BE MADE A SPECIALITY AT OUR GENERAL HOSPITALS?

To the Editor of THE LANCET.

SIR,—Any proposal for extending the teaching capacity of our general hospitals so as to provide more thorough grounding for students in a subject which is certain to occupy a very large share of their attention as general practitioners deserves careful consideration. At the same time it must not be supposed that any radical change in the corporate teaching of our medical schools is required. The healthy rivalry which has for many years existed between the different metropolitan schools has had the effect of securing for most of them a very efficient staff of lecturers and teachers. By the gradual introduction from time to time of more practical teaching the students have been brought face to face with subjects which require close individual study, and it has been found much easier to impress their minds with the minutest details of medical science. The lecturer on physiology, for instance, finds his task much lightened, knowing that by practical demonstrations in the laboratory he can teach through the eye and hand, as well as the ear,

truths which if only once heard are very likely "to slip the memory." As a rule students have neither time nor inclination to attend the clinics at the special hospitals. It has, therefore, been found necessary to establish special departments at our general hospitals for the study of diseases of the eye, ear, skin, and throat, &c. Not that these subjects were passed over in the previous arrangements for a complete curriculum, but that with the growth of knowledge it was found necessary to isolate each subject and appoint a separate teacher for each department. Those who have devoted much attention to the study and treatment of diseases of children will, I think, be ready to endorse what I have said as to the importance of making this a separate department at our larger hospitals. I shall doubtless be met by the objection, "Where do you propose to draw your line up to which the symptoms and treatment would be as for children, and beyond which the patient must be treated as an adult?" The answer is obvious—viz., that as "nature abhors a vacuum," so does she hate definitions. It is equally obvious that ranged on either side of puberty are patients placed under the same external conditions, suffering from the same exciting causes, but requiring treatment of a very diverse character, and that because of the vastly different constitutions and susceptibilities of children and adults. If I need to give an illustration, it is furnished by the carefully constructed tables of doses in our materia medica according to the standard of age. The student naturally infers from this that, given the general symptoms of a disease, it only requires to measure out the quantity, and not the quality, of the treatment in proportion to the age of the recipient. A casual perusal of the examination papers suffices to show that this is the *fons et origo mali* requiring consideration and amendment.

Before proceeding to define the details of the change which seem to be desirable, I must clear the ground by stating generally what provision is now made for students to acquire a knowledge of the injuries and diseases peculiar to children, of the symptoms which specially characterise the manifestations of disease and injury at all ages, and of the importance to be attached to correlative signs and symptoms as regards diagnosis, prognosis, and treatment, with a view to defining the distinct method of treatment in certain cases of the same disease in children as distinguished from adults. At many of our general hospitals there are special wards for children, but this seems designed more as a convenience than for special study. I am not aware that at any hospital a course of lectures is given on the diseases of children, either clinical or systematic.

At every medical school the obstetric physician includes in his syllabus of lectures "the diseases of children," or at least he is regarded as the authority on this subject. The reason, I suppose, for amalgamating these two departments under the superintendence of the professor of gynaecology is that the expert who undertakes the responsibility of divorcing a woman from her child is considered the proper person to medically superintend the early months of its independent existence. I can also understand why the obstetric physician claims to wield the *armamentarium chirurgicum* in cases of abdominal tumour affecting women. It is quite another question whether this is a wise and proper division of labour. The teaching of obstetrics and gynaecology is a subject so vast and wide that little opportunity can be left for discoursing upon the diseases of children or upon the surgical treatment of abdominal tumour. I cannot but think such "a triple alliance" is calculated to prove disastrous both to the teacher and the taught. Physicians are not allowed to dispense medicines; why not restrict their use of surgical instruments? Then, as regards surgical diseases of children: do they not require special study? With the gradual introduction of "arms of precision" as aids to diagnosis, it might be thought that the *tactus eruditus* of the surgeon would be required for the delicate handling of such instruments.

I do not know exactly how much knowledge of pathology a surgeon is supposed to possess; but this I know, that little by little the physicians are claiming authority over diseases which have always been considered to belong to the special domain of the surgeon; and this just in proportion as the local manifestation becomes subordinate to the constitutional taint. Diseases of the throat and skin have gone, membranous croup becomes diphtheria by the same migratory process, rickets is about to surrender its former allegiance, syphilis is a febrile disorder requiring a siege train of medi-

experts and police to compass its downfall, and internal wars, so far as "the better half" of mankind is concerned, fall before the knife of the obstetric physician. The son will soon have nothing left to appraise himself with joint disease, stricture, hæmorrhoids, and tumours. I expect to save a general stampede, and the public from being cajoled into the idea that operating surgeons are only justified to use a knife, and that very sparingly. A conference of hospital surgeons and physicians might with advantage take this in hand and appoint a committee to draw up a list of diseases, arranged under different headings, and then approved the list could be printed and suspended in waiting-rooms of hospitals to enable the executive to classify the patients according to a recognised plan. In the absence of such a system of classification great mistakes are made, time is lost in transferring the patients from one department to another, and occasional disagreements between colleagues are engendered thereby. At our general hospitals no attempt is as a rule made to treat the children separate from adults in the out-patient department. The sights and sounds which meet the eye and ear of children at often be very prejudicial to their moral and physical well-being.

I would sum up my arguments in favour of the establishment of a separate department for children as follows:—The arguments in favour of any speciality having a separate department apply equally and more forcibly as regards children. 2. Students acquire imperfect ideas as to the specific nature and treatment of disease in children when these are prescribed for at the same time as adults, having no united time for proper classification. 3. It is most important to give students special facilities for becoming acquainted with the diseases of children, as these must constitute the bulk of their practice in after-life. 4. The testimony of those who have held clinical appointments at hospitals for children is that the knowledge thus acquired of a very different character from that usually obtainable at our general hospitals. 5. The present time seems opportune for making such a change, when a new nomenclature is being prepared, as it would be the first step in the direction of a scientific classification of medical and surgical diseases. 6. The fact of assigning medical diseases to young children to the care of the obstetric physician leaves the corresponding surgical diseases unprovided for specially. 7. In the diseases and injuries of children the symptoms are so markedly characteristic, and the treatment and general management of the little patients are so different that a special department seems a natural sequence. 8. The pathology of diseases of children would receive a fresh impetus, and scientific surgery would gain by the change.

Surgeons must not think that my proposal would involve the surrender of some of their possessions. On the contrary, by a proper classification of diseases many more would come under their superintendence. If one hospital surgeon undertakes the charge of all children under eight or ten years of age, the other surgeons will divide amongst them the surgery of adults, and thus the work is reorganised, and the students reap the benefit of the change as well as the patients. What I desire to advocate is a short course of lectures on the diseases of children, and a proper classification of diseases—medical and surgical.

Meanwhile I think I might say, on behalf of myself and my colleagues at the Victoria Hospital, that we shall be happy to welcome all students who desire to attend our clinics for the purpose of studying the diseases of children.

I am, Sir, your obedient servant,  
FREDERICK CHURCHILL, M.B.

Cranley-gardens, S.W., Oct. 1882.

## THE CONTAGIOUS DISEASES ACTS.

To the Editor of THE LANCET.

SIR,—Dr. Macnamara seems to imagine that a Lock Hospital under the Contagious Diseases Acts, and a voluntary Lock Hospital, are one and the same thing. He probably never made a greater mistake in his life. In voluntary hospitals like the Dublin Westmoreland Lock, a female patient is free to come and go. She gets such treatment as she requires, and no doubt gratefully listens to such gentle admonition and advice as may be tendered by the chaplain

and others. But it is a very different matter in the Lock Hospitals under the Contagious Diseases Acts. No woman can be admitted there unless she is registered as a common prostitute, and subjected to medical introspection. Do you know what registration as a prostitute means? What Dante wrote over the gates of hell—"Abandon hope, who enter here!" It means, in the words of the talented editor of the *Westminster Review*, "Ostensible social degradation; it sets upon them the mark of infamy; it compels them to commit themselves absolutely to a life of prostitution as a condition of continuing to exist." It is, in the words of Dr. Mireur, of Marseilles (see his great work on Prostitution), "the sinister stroke by which women are cut off from society, and after which they no longer belong to themselves, but become merely the thing of the administration; they are cut off not from society only, but from heaven, from hope, and from the power to repent." Now, if Dr. Macnamara wished to prevent women from applying for treatment when diseased, he surely could not devise a more effectual deterrent than this; in fact, so great is women's abhorrence of the system that only one in ten, or one in seven, of undoubted prostitutes can be forced upon the register either here or elsewhere. Dr. Macnamara seems to fancy that the few who are forced upon the register may be reformed when in hospital, but they must be diseased first, or they would not be sent to hospital, and surely that is not a desirable consummation. Moreover, the unanimous testimony of the whole of the rescue societies is that when women have been brutalised by periodical introspection, it is impossible to reform them. Let anyone who doubts this statement drop a post-card to the Rescue Society, 85, Queen-street, Cheap-side, London, and utilise the information he will receive in reply. As to the advanced stage of disease in which some women apply for treatment, there are many circumstances to be considered before we can pronounce an opinion on such conduct. Perhaps the woman did not know of the existence of the Lock Hospital, or was little aware of the kind treatment she would receive under Dr. Macnamara's skilful care. To make the most of such institutions information must be diffused; women must have every inducement to come forward, and none to turn away. The doors must be as it were always open, but they must be opened by Christian charity, and not by the police. The advanced stage of disease to be observed on the voluntary side of the London Lock is entirely owing to the want of accommodation; the cases are so largely in excess of the number of beds, that only the worst can be admitted. As the late Mr. Acton remarked, "The prize of a bed was offered to successful severity, and therefore it is no wonder that bad cases are to be seen in voluntary Lock Hospitals." In fact, Dr. Macnamara's evidence, if he did but know it, is all in favour of voluntary Lock Hospitals, and dead against the Contagious Diseases Acts. Balzac used to say that it was impossible to reform a woman but by the influence of a passion and a sentiment—love and religion; and such cynics, I am afraid, would laugh at Dr. Macnamara's tales of reformation. Let that be as it may, however, my experience has taught me that the lowest harlot is quite as anxious to be cured of venereal disease as any peer of the realms; I should say more so. And I am sure that voluntary institutions, well conducted, will accomplish infinitely more good than any vain and aggravating efforts at police control.

I am, Sir, your obedient servant,  
EDGAR BECKETT TRUMAN, M.D.,  
Physician to the Hospital for Women, Nottingham.  
Nottingham, October 31st, 1882.

## NEWCASTLE-ON-TYNE.

(From our own Correspondent.)

THE Medical Officer of Health for the borough has presented a report as to the presence of zymotic diseases in Newcastle during the fortnight ending Oct. 28th, 1882, of which the following is a summary:—Small-pox 32 cases, enteric fever 28, scarlet fever 42, typhus 7, diphtheria 1, continued fever 1. Upon the whole, as regards zymotic diseases, there had been a decrease of seven on the previous fortnightly return. Scarlet fever is still epidemic at Walker, where there had been ten deaths during the last month;

also some cases of small-pox. At Wallsend there had been several cases of scarlet fever, two proving fatal.

At Gateshead the subject of whitelead poisoning has very properly occupied the attention of the authorities, and at the board of guardians it was stated that cases of poisoning came under notice every week. After some discussion a memorial was presented to the Local Government Board, calling its attention to the serious loss of life and injury to health involved in the employment of females at whitelead works, and suggesting the expediency of regular medical attendance being made at such works, and the necessity of machinery being introduced to do the most dangerous part of the operations. It was mentioned in the discussion that when visits of inspection were made to lead works attention was called to a class of persons who had been employed at them for years, and who still enjoyed good health; but if inquiry was made into the nature of the work these people performed, it was quite different from that done by the poor people who suffered from lead-poisoning, and thus became a burden to the ratepayers. This request of the guardians seems to be a reasonable one. The worst of the whitelead manufacture is that the most dangerous part of the operations is carried on by the hands of females and young persons, who are naturally less able to resist the subtle influence of the poison.

There was a very interesting meeting held here on last Tuesday night of the North of England Microscopical Society, Mr. Mason Watson, treasurer, in the chair. Mr. N. H. Martin exhibited "Coles' Studies in Microscopical Science," comprising histological, botanical, and petrological preparations, with photographs and descriptions. The care with which these preparations were mounted excited admiration in the members present, and their general fidelity to nature was freely admitted; at the same time, from the conversation which ensued, it would appear that some of the speakers considered that the practice of staining microscopical preparations was open to some objections; at all events it was thought that staining should never be resorted to for mere ornament, and from a microscopical point of view was only allowable when, from chemical action or otherwise, it rendered structures more distinct. The Society, which is connected with the Royal Microscopical, is doing a good but quiet work in creating and fostering a love of natural science through microscopical pursuit.

The Bishop of Newcastle is making his presence felt here. The other day he made the round of the infirmary with Mrs. Wilberforce, and the other night he presided at a flower mission concert—that is, a very useful organisation whereby flowers are collected and distributed to poor patients laid up in our medical charities and elsewhere. Yesterday he preached, at the Cathedral of St. Nicholas, to the Mayor and Corporation. On this occasion the ceremony of "churching the Mayor," as it is called, takes place, and the collection, a good one, was taken in aid of the Hospital Sunday Fund. He made some pointed allusions to our profession; indeed, the bishop is evidently a working one, constantly taking part in aiding some of our charitable or philanthropical societies.

It is stated in our newspapers that the recently closed sanitary exhibition here was not a financial success. Various causes are assigned for this, such as the great popularity of the Tynemouth Exhibition, which was held at the same time, and which drew an attendance of upwards of 150,000 persons. Then, again, an impression had got abroad that the exhibits were commonplace and uninteresting, than which nothing could be more absurd, but the public taste is a curious thing and very difficult to discover, as many have found out to their cost. The exhibition building was placed in a most awkward and out-of-the-way situation, and this may have had something to do with the failure. The exhibition itself was most varied, instructive, and useful, and you will be glad to hear that many of the enterprising exhibitors were well rewarded for their trouble and expense in receiving a large number of orders for their manufactures.

A course of ambulance lectures is announced to begin here to-day by Mr. G. E. Williamson, assistant-surgeon to the infirmary, and having charge of the ophthalmic department there. The lectures are to be illustrated by the lantern and other means. The subject has fallen into good hands, and is certain to be well and lucidly treated by Mr. Williamson.

Newcastle-on-Tyne, Nov. 12th, 1882.

## SCOTTISH NOTES.

(From our own Correspondent.)

JUDGING from Professor Pettigrew's introductory, and Professor M'Intosh's magnificent address at St. Andrews, the teachers in the science side are determined to shake the dry bones of that ancient, but somewhat somnolent, seat of learning. Professor Pettigrew strongly animadverted upon the almost complete want of encouragement given to science studies, passed a high eulogium upon these as helps to the highest culture, and eloquently argued for increased scope being given to work in the arts department, so that men might know something of themselves, and of what passes around them. I hope that the college authorities, for whom evidently the address was primarily intended, will, in laying their claims before the intended Executive Commission, give due heed to Dr. Pettigrew's suggestions. St. Andrews is at present threatened with death from general atrophy, and if there is any chance of rejuvenescence, it is probably through the help of science that vigour can be restored.

Dr. M'Intosh met a large audience of students and friends—chiefly the latter I fear—on Monday, and gave a summary of work done in marine zoology, in which he showed what a wonderful advance has recently been made. The simple quotation of Professor Edward Forbes' dictum, that animal life probably ceased at a depth of 300 fathoms, and the remembrance of the almost innumerable specimens obtained by the *Challenger* and other expeditions, at depths as great as from one to five miles, are sufficient to indicate the strides recently taken in this department of observation. Dr. M'Intosh went on to show the absolute want of zoological stations along our coast, forgetting evidently to refer to Dr. Cossar Ewart's successful efforts in this direction at Aberdeen, and proceeded to argue in favour of the equipment of several of these, but more especially one placed near the bay of St. Andrews, so rich in animal and vegetable life. This work is one demanding serious effort, and Dr. M'Intosh's enthusiasm could not lead him in a direction likely to be more profitable to science.

The Duke of Buccleuch, with his usual liberality towards the districts with which he is connected, has provided Dalkeith with an elegant and commodious hospital. The building was thrown open for public inspection a few days ago, and is now ready for the reception of patients. Consisting of two storeys, the upper floor is divided into airy and agreeable wards, which are capable of accommodating about fifty patients. Means of isolation for infectious cases are provided by a suitable arrangement of the wards, and the existence of separate staircases. The necessary accommodation for the staff of nurses and the efficient working of the institution is provided on the ground-floor, and recent improvements have been freely utilised. Ventilation, both of the house and the drainage system, has been carefully considered, and, as a further hygienic advantage to the inmates, a large space of ground has been left for outdoor recreation. The police commissioners of the borough have suitably furnished the hospital, which has been handed over to them for the use of the inhabitants.

The centenary of the Montrose Royal Asylum and the recent extensive addition to the accommodation provided for patients there, have been taken by the Directors as a fitting opportunity for showing their continued confidence in Dr. Howden, the physician-superintendent, and they have raised his salary from £700 to £850.

After litigation in the English Court, it has been decided that the terms of Dr. Donald Fraser's bequest do not entitle the Scottish Society for the Prevention of Cruelty to Animals to the £10,000 claimed. The treasurer and trustees of the Donald Fraser Bequest to the Blind at Inverness were named as residuary legatees, and the decision of Mr. Justice Fry is that they have established their claim. If my memory serves me aright, the handsome legacy in dispute is that which, originally intended for the University of Edinburgh, was otherwise disposed of on account of Dr. Fraser's objection to the experiments upon animals supposed to be carried on in the institution named.

Various local scientific societies have recently held their first meeting for the season. The activity of the Perthshire Society of Natural Science is specially noteworthy, and

be commended to gentlemen interested in similar ties elsewhere. After much exertion on the part of the Council, the friends of the Society were induced to subscribe in of over £2000 for the purpose of securing suitable rises as museums, lecture-rooms, &c., and since the building was opened a few months ago, the members have been most assiduous in furnishing specimens for the museum with the intention of having a complete collection illustrating the Perthshire natural history. In the interest of science generally, local societies are much more profitably engaged in establishing good local collections than in getting together a feeble imitation of our great natural history museums; and when intelligently guided, as the Perthshire says has been by men like the present Professor Geikie of Edinburgh, and Dr. Buchanan White, F.L.S., of Perth, such associations may be of the greatest value in completing knowledge of the fauna and flora of our country.

Mr. Wragg has again completed for the year his work at the Meteorological Observatory on Ben Nevis, the highest station in Great Britain. Though his work is so well known, its importance appreciated by all interested in the subject, it appears that the Scottish Meteorological Society is at the utmost difficulty in providing the necessary funds for the erection of a permanent observatory; and for its total endowment £5000 is the sum required, and it will be unfortunate if such a valuable agency must be dropped without the want of timely pecuniary assistance.

### ITALIAN NOTES.

(From our own Correspondent.)

THE elections under the extended suffrage and the *scrutin* *liste* have wrought little change in the composition of Parliament, except in the greater number of professional candidates who have been returned. Like other continental nations, Italy sees no incompatibility between medical practice and a seat in the Legislature, and, as in Germany, Austria, Hungary, France, and Spain, she counts among her most active and able public men the consultant physician and the occupant of the University Chair. Between twenty and thirty representatives of her various professions, exclusive of that of law, are now also members of the Chamber of Deputies, to say nothing of the scientific and literary phalanx which reinforces her Upper House. Her Minister of Public Instruction is Dr. Guido Baccelli, one of the leading consultants in the Peninsula; and a prominent debater of the opposition is Dr. Tommaso-Crudeli, whose researches in pathology shed lustre on the *sapienza*, and in a published form, dedicated to his master Virchow, are now engrossing the attention of other schools. The first volume, entitled *Istituzioni di Anatomia Patologica*, containing his maturer work on germinal miasms—particularly malarial infection—was as much to interest the thoughtful practitioner at home and abroad. With the universal recognition of public hygiene as one of the legislator's primary subjects, the presence of such men in any Parliament is more than justified; while cognate questions like the extinction of the phylloxera pestatrix and the prevention of floods, peculiarly urgent in Italy, would of themselves account for the preponderance of the scientific element in her Chamber.

Thanks, indeed, to such inspiration, the Italian Government has drawn a cordon round the vine-culture—a blockade which the phylloxera has not yet been able to run. The floods are, however, a more grievous opprobrium of public hygiene than ever, mainly from their prevention having been treated as exclusively a question of engineering. The destruction of forests, whether by the woodcutter or by frost or conflagration, is chiefly to blame for the heavy localised rainfall, which, in the Alta Italia, swells the mountain-streams in a few hours to torrents and the lowland rivers to lagoons. Of what avail is the engineer's embankment when the hillside, denuded of its forest, sends down the water in tons instead of gallons, and the swollen affluents contribute to the main streams in proportional excess of their hitherto estimated volume? For such visitations the remedy is not mechanical, but physical—the restitution to the uplands of their despoiled verdure, and with it the means of detaining and distributing the moisture and regulating the rainfall. Italy has, at length, awakened to this necessity

and is encouraging the plantation of trees, particularly the eucalyptus, in appropriate places, holding out substantial rewards to the landowners who succeed best in clothing the hillsides with wood. The example of her French neighbour is having a wholesome effect upon her. Twenty years ago, or rather more, Savoy passed from her to France, and took with it the *damnsa hereditas* of autumnal inundations due to the reckless destruction of forests. The Emperor Napoleon immediately set himself to avert these unwelcome visitants, and restored to the old sub-Alpine territory its former pride of waving woods and lustrous foliage. In ten years Savoy was its former self again, and, thanks to its plantations, the floods that have visited it since 1872 have done but little material damage, in striking contrast with the desolation and misery they annually cause to the Italian motherland.

After the floods, the pellagra. This scourge, which was to have been abolished with the grist-tax, is now worse than during its incidence, and the physicians and philanthropists of the pellagrose districts have founded a society of prevention and cure. Its prospectus is before me, and provision is first to be made for the relief, and if possible, the restoration to health of the actual sufferers, and next for the removal, or at least the minimising, of the conditions under which the malady originates and spreads. For the former end, the pellagrose subjects are to have systematic treatment, according to the method of Lombrosi, in their homes or in hospital, while their children are to receive artificial lactation. For the latter end a hot-air drying apparatus is to be instituted for the garnered maize, and the Anelli oven is to be employed wherever practicable; the "economic kitchen," already in working, is to be extended and maintained; the feeding of the peasantry is to be watched, particularly to prevent the consumption of spoiled maize; and instruction is to be given in cleanliness of person and of home, and to make the people as far as possible the intelligent custodians of their own health. To carry out these provisions, resources are drawn from the Government, from the provincial and communal funds, from the donations of private individuals, and from the annual subscriptions of the associates. These latter are divided into two classes of both sexes, the active and the contributing: the active will charge themselves with the artificial lactation of the children, with the care of the pellagrose, and with the hygiene of the peasantry; while the contributing will subscribe at the rate of six francs a year. I expect to have soon a favourable report of this urgently needed and well-organised society.

The University of Palermo adds another to its specimens of teratology. In the neighbouring Castellbuono a woman was lately delivered of a female child with two heads well planted on the trunk, symmetrically proportioned, and with regular articulations, after a normal gestation of nine months. One head and the left arm presented first; but for several hours no further progress was made, and the child (such is the custom) received baptism. It was dead before the arrival of the surgeon, who, on extricating it, found the first head with the tongue protruding, and firmly fixed between the lips, the eyes also protruding, in token of the evident asphyxia. The second head was in the same condition, while the upper region of the trunk, in correspondence with the median point of the heads, was deeply lacerated down to the abdomen; the laceration was due to the forcible delivery necessitated by the resistance of the second head. The unfortunate mother died after forty-eight hours' suffering.

Rome, Nov. 6th, 1882.

### MEDICAL TRIALS.

CITY OF LONDON COURT.—NOVEMBER 4TH.

(Before Mr. Commissioner KERR.)

RECOVERY OF CHARGES FOR SERVICES RENDERED BY UNQUALIFIED ASSISTANTS.

BLOCK v. POETTING.

THIS was an action in which Mr. Moses Block, doctor of medicine, of 19, Chiswell-street, sought to recover from Mr. Richard Poetting, of 6, New Basinghall-street, the sum of £3 3s. for medical services rendered. Mr. Pease, solicitor, appeared for the plaintiff, and Mr. Lawrence, solicitor, for the defendant.

Mr. Emile Bransome, the plaintiff's assistant, said that

the charges were fair and reasonable, and that the defendant had been attended by himself and his employer.—His Honour: Are you a qualified medical practitioner?—Witness: No, but my employer is.—His Honour: But did you attend the defendant?—Witness: Yes, on behalf of Mr. Block.—His Honour: You had no right to do so.—Mr. Pease: Is this not a similar case to that of a clerk attending for a solicitor?—His Honour: No; the law says that a doctor cannot recover for medical advice given by his assistant.—Mr. Pease: But here the plaintiff is instructed; and sometimes he called upon the defendant, and sometimes the assistant did.—Mr. Lawrence: But did Mr. Block do all the work?—Witness: No; but he saw defendant several times during his illness.—Mr. Pease: Surely, your Honour, this is a monstrous defence?—His Honour: Indeed it is not.—Mr. Pease: Why should a medical man be compelled to call personally on a patient any more than a solicitor or counsel upon his client?—His Honour: Lawyers, unfortunately, are allowed to do extraordinary things. The law, however, says that if a doctor send his assistant to a patient the assistant must be qualified. I must find for the defendant; but will give leave to appeal if you like.—Mr. Pease: The defendant does not deny that he was attended.—Witness: And he preferred to be attended by me as he knew me.—His Honour: That only makes the case worse. I may tell you that you are liable to be indicted, and perhaps you will be so some of these days, if anything goes wrong.

Judgment was then given for the defendant with costs.

### MEDICAL NOTES IN PARLIAMENT.

In the House of Commons, on Thursday, the 9th inst., the report was presented of the Commission appointed to inquire into the subject of Criminal Lunacy; as was also a return of the number of deaths on board emigrant ships.

On Monday, Mr. Biggar gave notice of a series of questions as to the removal from Belfast Asylum to the workhouse of an inmate named Nelson; and Dr. Cameron intimated that he will question the Lord Advocate with regard to the diversity of powers of sanitary supervision and administration granted to local authorities in Scotland.

#### *Union Medical Officers.*

Dr. Farquharson asked the President of the Local Government Board whether his attention had been drawn to the case of "Grubb v. the Chesterton Board of Guardians," and the decision and comments of the Cambridge County Court judge thereon; whether the Local Government Board would modify their consolidated orders so as to prevent in future the contingency of a district medical officer summoning his board of guardians to pay him his extra fees; and whether he would lay upon the table of the House a copy of the correspondence between Dr. Martin O'Connor of Chatteris, Cambridgeshire, the Local Government Board, and the North Witchford Board of Guardians, Cambridgeshire, relative to the refusal of the latter body to pay a fee claimed by Dr. Martin O'Connor.—Mr. Dodson said he had seen the newspaper report of this case, in which a Poor-law medical officer obtained judgment for extra medical fees for attending a poor woman who had met with an accident. In regard to the proposed modification of the general order, it did not appear to him that the Local Government Board could so alter it as to prevent a medical officer taking legal proceedings against a board of guardians for extra medical fees if they declined to pay, or, on the other hand, require the guardians to pay such fees when not legally due. In regard to the correspondence, that would be produced if the hon. member liked to move for it.

#### *Vaccination.*

Mr. Hopwood asked the President of the Local Government Board in regard to the alleged inoculation of French soldiers with disease by vaccination, which occurred in December, 1880; whether he would think it right to lay upon the table all the information he had obtained on the subject.—Mr. Dodson said he could only repeat that the information which he obtained was so incomplete that it threw no further light on the subject, and he saw no advantage in laying it on the table of the House as it stood. At the same time, he was as anxious as his hon. and learned friend could be to obtain full particulars on the subject, and he had again requested the Foreign Office to endeavour to

ascertain whether the French Government had made any further inquiries into the matter, and to afford the Local Government Board further knowledge on the subject.

Mr. A. Moore gave notice of a question relating to the reports received by the Irish Local Government Board as to the state of the emigrants' lodging-houses in Londonderry; and Lord George Hamilton intimated that he will make inquiry as to the refusal of the English Local Government Board to allow the Whitechapel Board of Guardians the means of obtaining a periodical inspection of the homes of boarded-out children.

On Thursday, in reply to Mr. Healy, Mr. Trevelyan explained that although the salaries of Irish coroners were payable half-yearly, the county treasurers usually deferred payment until the eve of the next assizes, when they had the necessary funds in hand.

#### *Health of the Troops in Egypt.*

Mr. Childers, replying to Sir H. Tylor, stated that the present percentages of sickness amongst the army of occupation in Egypt were 7 per cent. amongst the infantry and cavalry, and 11 per cent. amongst the artillery; but these percentages were gradually diminishing as the sicknesses of individuals came to an end. Sir Andrew Clark went to Egypt a week ago to inquire whether any improvements were desirable in the barrack arrangements and hospital accommodation; and meanwhile no expenditure on those services had been spared.

#### *The Army Medical Department in Egypt.*

Sir T. Lawrence asked the Secretary of State for War why the name of Surgeon-General Hanbury, commanding the Medical branch of the Egyptian Expedition, was omitted from the Parliamentary Vote of Thanks to the general officers and others of the Expedition; whether Surgeon-General Hanbury did not hold the relative rank of Major-General, and was of the same rank as the other Major-Generals whose distinguished services were specially acknowledged in the despatches of the General the Commander-in-Chief of the Expedition; and why the names of Deputy Surgeon-General Colvin Smith and the medical officers of the Indian Contingent were omitted from the despatches recommending the promotion of medical officers in the last despatch of the General Commanding-in-Chief.—Mr. Childers had to say, speaking on behalf of the First Lord of the Treasury and the First Lord of the Admiralty, who, with himself, were responsible for the language of the Vote of Thanks, that they followed the precedents, according to which it was not usual to mention departmental officers. He saw no reason for enlarging the already long list of names. As to the second question, it was true that Surgeon-General Hanbury held the relative rank of major-general. As to the third question, it was not for him to ask the Commander-in-Chief of an army why he either excluded or included in his despatches the names of particular officers, but, as a matter of fact, Sir Garnet Wolseley wrote a supplemental despatch, which would appear to-morrow, and in which he observed the name of Deputy Surgeon-General Colvin Smith.

#### *Prevention of Floods.*

In reply to Mr. Peel and Sir A. Otway, Mr. Dodson said he was aware of the damage and sickness caused by the floods at Strood and elsewhere, and he was fully sensible of the importance of giving the inhabitants of river basins power to avert these evils, but he was not now prepared to state what course the Government would pursue.

#### *The Attempt to Shoot Judge Lawson.*

Mr. W. Corbet asked the Chief Secretary for Ireland, having regard to the antecedents of the man Patrick Delany, and the circumstances under which he had been arrested on a charge of attempting to shoot Mr. Justice Lawson, whether he would direct a medical examination as to the mental condition of the prisoner.—Mr. Trevelyan said he had no intention of interfering with a matter which was already fully provided for by law.

PRELIMINARY steps have been taken towards the establishment of a cottage hospital at Abingdon. The sum of £638 has already been collected for the purpose, and a subscription of £50 per annum for the two or three years from the starting of the hospital has been promised.

## Medical News.

**ROYAL COLLEGE OF PHYSICIANS OF LONDON.**—The following gentlemen passed the Primary Examination: the Licence on the 9th inst.:

John Geo Adams, William Rushworth Ashworth, Charles Barlow, Thomas David Collis Barry, Lancelot Bathurst, Robert Sewell Batson, Reginald Treacher Bowden, Albert Bowhay, Joseph Thos. Boyd, Jabez Pratt Brooks, Samuel John Brooks, Robert Marston Bruce, Leopold Burroughs, Wm. Arthur Cahill, Herbert Bertram Cavell, Herbert William Chambers, Arthur Fredk. Gambell Codd, Arthur Wandesforde Comber, Charles Thomas Thornton Comber, Arthur Zell Claydon Cressay, Arthur Crossley, Domingo Antonio De Montbrun, Pedro Louis De Montbrun, John Patrick Cronly Dillon, Arthur Herbert Dodd, Walter Harry Dodd, Joseph Bowerman Drew, Herbert Ebenezer Edlin, Dennis Cawood Embleton, Henry Collen Ensor, Charles Ewart, Courtenay Jas. Fuller, Thomas Frederick Gardner, Gustavus Geo. Gidley, Charles Ernest Goddard, John Harley Gough, Walter Spencer Anderson Griffith, Harry Harlock, John William Harris, Hilary William Haydon, Harry George Henderson, George Frederick Hentsch, Hugh Gardner Hill, Chas. John Holton, George Hope, Joseph Duncan Howe, Francis Rowland Humphreys, Edwin Guy Hunt, Alfred William Hunton, Edward Jessop, Eugene Numa Joly, Hedley Gordon Jones, John Edw. Evans Jones, Herbert Arthur Kent, Charles Edw. Liesching, William Leppingwell Livermore, Arthur Maude, Charles Metzgar, John Perrett Millington, Henry Geo. Hawkins Monk, Joseph John Oakman, Harry Marmaduke Page, Herbert Lloyd Parry, Edmond Wm. Paul, Edmund John Penny, Alfred Ernest Albert Pettingill, Ernest Willmer Phillips, George Gordon Owen Phillips, Josiah Northey Phillips, Richard Pinhorn, Alexander Yates Reilly, Herbert Ellis Rowell, John Jones Rowland, George Jervis Rugg, Charles John Sharp, Albert Smith, John Henry Spitzly, Hubert Samuel Stockton, Henry John Thornton, Hugh Champneys Thurston, Rankai Totsuka, Geoffrey Frederick Travers, Edward Tull Trevor, Frederick Wenman Turtle, Thomas Unicorn, Arthur Wm. Wheatly, William Whitworth, John Grant Wilson, Harrie Yeo, Wm. Hamond Young.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—The following gentlemen, having passed the required examination for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on Monday last:

Atkins, George, L.R.C.P. Lond., Yealmpton, Devon.  
Baker, William Brain, L.S.A., Banbury.  
Boxall, Robert, L.R.C.P., Cranleigh, Surrey.  
Bromley, Henry Urgent, Braintree.  
Butterworth, Samuel, L.R.C.P. Edin., Rochdale.  
Coombe, Charles Frederick, Wrothing.  
Furnival, Francis Henry, L.S.A., Nottingham.  
Heathcote, Ralph George, L.R.C.P. Edin., Manchester.  
Herman, Christian Lawrence, M.B. Edin., Cape Town.  
Lister, Joseph Herbert, L.S.A., Hantley-street.  
Littlewood, John Oacrott, L.S.A., Sutton-in-Ashfield.  
Priestley, John, L.S.A., Greenheys.  
Shirley, Matthew Bernard, L.R.C.P. Edin., Leeds.  
Smith, W. A. Winwood, L.S.A., Kensington-gardens-square.  
Statham, Reginald Whiteside, L.S.A., Walsworth.  
Waring, John Arkle, L.R.C.P. Edin., Prince's-gardens.  
Wilson, George, M.B. Edin., Lockerbie, N.B.  
Wyborn, Samuel, L.S.A., Windsor.

The following gentlemen were admitted Members of the College on Tuesday last:

Aslanian, Bedros, L.S.A., Van, Turkey.  
Banham, William Wilfred, Barnsley.  
Beauley, William Crump, M.B. Dub., Bloomsbury-square.  
Bown, Arthur Thomas, Bath.  
Dacre, John, Leeds.  
Dale, Walter Frederick, L.R.C.P. Lond., Coleshill.  
Guinness, Thomas Archibald, Greville-place.  
Harriss, Henry Jones, Filton, near Carmarthen.  
Hall, Alfred, Ashbourne.  
Hind, Wheelton, Honington, Suffolk.  
Hoar, C. de Sambler, Campden-hill-gardens.  
Horrocks, William Henry, Liverpool.  
Maye, John, L.S.A., Kingsbridge, Devon.  
Myles, James Percival, L.R.C.P. Lond., Bristol.  
Porter, Guy David, Abbey-gardens.  
Price, Thomas William, Birmingham.  
Salter, George Herbert, L.R.C.P. Edin., Mount-street.  
Smith, James Edward, L.S.A., Hammeramith.  
Sells, Hubert Thomas, Merrick-square.  
Sunderland, Septimus, Birmingham.  
Winder, William Henry, Manchester.

The following gentlemen were admitted Members of the College on Wednesday last:

Bailey, Charles Frederic, Norwich.  
Caiger, Frederick Ford, Gloucester-street.  
Cardwell, Thomas, Reading.  
Crick, William Thorne, L.R.C.P. Lond., Great Glen, Leicester.  
Cuff, Robert, Camden-road, Blackheath.  
Dakin, William Radford, Edith-road.  
Davis, John Warren, L.S.A., Milford Haven.  
Dun, Walter Angus, L.R.C.P. Lond., Cincinnati.  
Ellison, William Augustine, Windsor.  
Fraser, James Alexander, Blackheath.  
Harrison, John, L.R.C.P. Edin., Braintree.  
Hodges, Herbert Chamney, Walton, Herts.  
Kennings, William Munro, Newcastle.

Kinch, George Henry, L.R.C.P. Edin., Hilldrop-crescent.  
Leon, Greville Ewing, L.S.A., Hamilton, Bermudas.  
Masters, Edgar Ernest, Lewisham.  
Mead, Herbert Remington, L.R.C.P. Edin., Blackheath.  
Smith, Howard Lyon, Tollington-park.  
Taller, George Arthur, Brosley, Salop.  
Woodhouse, Alfred E. Clayton, Hanover-square.

Mr. Thomas Bryant, the newly elected member of the Court of Examiners, in the room of Mr. Birkett, took his seat at these meetings.

The following gentlemen passed the Primary Examination in Anatomy and Physiology at a meeting of the Board of Examiners on the 9th inst.:

H. B. Matthias, W. H. Pinches, H. C. Parsons, M. G. Robinson, and J. C. Barker, St. Bartholomew's Hospital; E. Goodall, Guy's Hospital; E. F. Jones and A. M. Whitehead, London Hospital; A. E. Read, St. George's and St. Thomas's Hospitals; J. Pieterse, F. Todd, F. I. Dewes, St. Thomas's Hospital; P. E. Maitland, Madras Medical College; J. J. Dickinson, London Hospital and Cambridge School; F. Farrow, Owens College.

Of the 90 candidates examined during last week, 23 failed to satisfy the Board, and were referred for three months' further anatomical and physiological study.

**APOTHECARIES' HALL.**—The following gentlemen passed the examination in the Science and Practice of Medicine, and received certificates to practise, on Nov. 9th:

Aslanian, Bedros, Dixon-street, L. Marsh.  
Holdsworth, William, Freeman-street, Grimsby.  
Jacob, Arthur Howard, Bernard-street, Russell-square.  
Llewellyn, James Davies, Glyn-neath, Glamorganshire.  
Mosse, Herbert Henry, Sutton, Surrey.  
Peckett, Arthur Wm. Chalmers, Burgoyne House, Southsea.  
Robinson, William, Great College-street.  
Sturges, Frank, Eckenham, Kent.  
Wheatly, Arthur William, Bralles, Warwickshire.  
Young, William Hy. Frome, Pastor-place, Brighton.

The following gentlemen also on the same day passed the Primary Professional Examination:—  
Norton Gilbert Gilkes, London Hospital; William Dymos Stevenson, Middlesex Hospital.

**ALDERMAN W. F. CROSKEY, M.D., C.M. Ed.,** has been elected Mayor of Lewes for the ensuing year.

**MISS ANNA GRAYDON** has left £1000 to the Adelaide Hospital, £500 to the Hospital for Incurables, and £500 to St. Mark's Ophthalmic Hospital.

An asylum for the poor in Halifax, N.S., caught fire at midnight, and thirty-five of the helpless inmates were burnt to death.

At the instance of the Pharmaceutical Society of Great Britain, a druggist was proceeded against last week at the Stockport County Court for describing himself over his door as "Analytical Chemist," he not being registered. The defendant was fined £5 and costs.

**VACCINATION GRANTS.**—The following gentlemen have received the Government grant for efficient vaccination in their respective districts:—V. Wanostrocht, M.B., of Eserick, York; Mr. C. W. Morris, Chipping Campden (fourth time).

**THE MEDICO-PSYCHOLOGICAL ASSOCIATION.**—The usual quarterly meeting of this Association was held at Bethlem Hospital on Wednesday evening, Nov. 8th. In the absence of the President, the chair was taken by Dr. D. Hack Tuke. Dr. Mercier read a paper on the "Conditions of Life affecting Insanity"; and Dr. Julius Mickle communicated some particulars on "Traumatic General Paralysis." An interesting discussion followed in each case, and, owing to the lateness of the hour, a paper by Dr. Fletcher Beach on "Atrophy of the Brain" was taken as read.

**HULL GENERAL INFIRMARY.**—The centenary of this charity was celebrated on the 12th inst. This hospital commenced as a temporary erection, and the present building in the form in which it was first raised was opened in 1784. In 1838 a large wing was placed at each end of the building at a cost of £3000; and more recently there have been added a new block at the back of the main portion, and several detached fever wards. The committee hope to raise £10,000 for the purpose of providing a convalescent home in connection with the infirmary. The meetings on the 12th were attended by several noblemen and influential residents of Hull, and in the evening a demonstration of the Friendly Societies of the town took place, the members of which were addressed by the Archbishop of York, who, in his wonted genial manner, commended the efforts made by the working people on behalf of the hospital, and gave them some good advice on the questions of temperance and thrift.

**THE MANCHESTER AND SALFORD SANITARY ASSOCIATION.**—The addresses to workpeople on subjects connected with health that were delivered last year under the direction of the Committee of the Manchester and Salford Sanitary Association are to be continued at intervals during the present winter, in addition to the series of "Health Lectures for the People," which are to be given in the Association Hall, Peter-street. The first of these addresses was on the subject "How to keep out the Cold," and was delivered on the 7th inst., at the goods yard of the London and North-Western Railway Company, London-road, by Dr. Ransome, lecturer on public health at Owens College. The audience consisted of about 150 workmen.

**METROPOLITAN ASYLUMS BOARD.**—At the meeting of the Board on the 11th inst. the reports of the Fever and Small-pox Hospitals were presented. These showed that in regard to fever cases in the fortnight, 42 had been admitted to Stockwell, 70 to Homerton, and 14 to Fulham, while 12 convalescents had been transferred to Hampstead. In all 154 fresh cases had been admitted in the fortnight, 21 had died in the same period, and 138 had been discharged, leaving 671 under treatment, as against 652 a fortnight ago. Of the whole number, 506 were scarlet fever cases, 37 were typhus cases, and 123 were cases of enteric fever. In respect to small-pox, only 15 cases had been admitted in the fortnight, 5 had died, and 15 had been discharged, leaving 68 under treatment, a decrease of 9 on the number remaining a fortnight ago.

## Medical Appointments.

*Intimations for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning at the latest.*

**ALPIN, WILLIAM, M.R.C.S., L.R.C.P.Lond.,** has been appointed Senior House-Surgeon to the Metropolitan Free Hospital, vice A. Cohen, M.D., B.Ch., resigned.

**ANDREW, WILLIAM, M.B., M.Ch.Ed.,** has been appointed Medical Officer for the Fourth District of the Lancashire Union.

**ANNES, F. R., M.R.C.S.,** has been appointed Junior House-Surgeon to the Metropolitan Free Hospital, vice W. Alpin, M.R.C.S., L.R.C.P.Lond.

**ASHE, ST. GEORGE, L.R.C.S.I.,** has been elected Medical Officer of the High-street Dispensary, South Dublin Union, vice Dr. E. H. Byrne, resigned.

**BARR, JOHN, M.B.,** has been appointed Medical Officer of Health to the Rialton Local Board, Lancashire.

**BARR, THOMAS, M.D., C.M., F.F.P.S.Glas.,** has been appointed Aural Surgeon to the Sick Children's Hospital, Glasgow.

**BROWN, J., L.R.C.P.Lond. &c.,** has been appointed Medical Officer of Health to the Borough of Bacup.

**BEATSON, GEO. THOMAS, M.D., C.M., L.R.C.S.Ed.,** has been appointed Extra Dispensary Surgeon to the Western Infirmary, Glasgow.

**BUCKLEY, HENRY CHILD, M.D., C.M.Aber., M.R.C.S., L.S.A.Lond.,** has been reappointed Medical Officer of Health for the Llanelli Urban Sanitary District.

**CAMERON, HECTOR CLARE, M.D., C.M., F.F.P.S.Glas.,** has been appointed Surgeon to the Sick Children's Hospital, Glasgow.

**CAMPBELL, WILLIAM, M.B., C.M.,** has been appointed House-Surgeon to the Royal Infirmary, Glasgow.

**CHRISTIE, JAMES, M.D., F.F.P.S.Glas.,** has been appointed Dispensary Physician to the Western Infirmary, Glasgow, vice Coats, resigned.

**COATS, JOSEPH, M.D., F.F.P.S.Glas.,** has been appointed Pathologist to the Sick Children's Hospital, Glasgow.

**DAVIDSON, JAMES H., M.B., C.M.Ed.,** has been appointed House-Surgeon to the Royal Infirmary, Glasgow.

**DUNN, THOMAS S., M.B., C.M.,** has been appointed House-Surgeon to the Royal Infirmary, Glasgow.

**EVANS, THOMAS, M.D., L.R.C.S.Ed.,** has been reappointed Medical Officer of Health for the Newquay Urban Sanitary District.

**FINLAYSON, JAMES, M.D., F.F.P.S.Glas., L.R.C.S.Ed.,** has been appointed Physician to the Sick Children's Hospital, Glasgow.

**FLEMING, WILLIAM JAMES, M.D., F.F.P.S.Glas.,** has been appointed Extra Surgeon to the Sick Children's Hospital, Glasgow.

**FORSYTH, ROBERT, M.D., M.Ch.Glas.,** has been appointed Medical Officer for the Birral District of the Dewsbury Union.

**GELLATLY, ANDREW, M.B., M.Ch.Ed.,** has been appointed Medical Officer for the First District of the Ashton-under-Lyne Union.

**GEMMELL, SAMSON, M.D., C.M., F.F.P.S.Glas.,** has been appointed Extra Physician to the Sick Children's Hospital, Glasgow.

**HUDSON, ERNEST, M.R.C.S., L.S.A.Lond.,** has been elected Junior Assistant House-Surgeon to the Sheffield Public Hospital and Dispensary, vice Mr. H. B. Fletcher, resigned.

**HUES, JAMES JOHN, M.R.C.S.,** has been appointed Medical Officer for the Handsworth District of the West Bromwich Union.

**JONES, B., M.R.C.S., L.R.C.P., &c.,** has been appointed an Honorary Surgeon to the Holloway and North Islington Dispensary, vice Scott, resigned.

**LAWRIE, WILLIAM J., M.B., C.M.,** has been appointed House-Surgeon to the Royal Infirmary, Glasgow.

**LEISHMAN, WILLIAM, M.D., F.F.P.S.Glas., L.R.C.S.Ed.,** has been appointed Physician to the Sick Children's Hospital, Glasgow.

**LUCAS, R. CLEMENT, M.B., B.S.Lond., F.R.C.S.Eng.,** has been appointed Surgeon to in-patients at the Evelina Hospital for Sick Children, vice Mr. W. Marrant Baker, resigned.

**MACEWEN, WILLIAM, M.D., C.M., F.F.P.S.Glas.,** has been appointed Surgeon to the Sick Children's Hospital, Glasgow.

**MENISH, JAMES, M.B., C.M.,** has been appointed House-Physician to the Royal Infirmary, Glasgow.

**MENIVER, E. ORR, M.B., C.M.Ed.,** has been appointed House-Physician to the Royal Infirmary, Glasgow.

**NEWMAN, DAVID, M.B., C.M., F.F.P.S.Glas.,** has been appointed Extra Dispensary Surgeon to the Western Infirmary, Glasgow.

**QUENNEL, JOHN COOPER, M.R.C.S., L.S.A.Lond.,** has been appointed Medical Officer of Health for the Ougar Rural Sanitary District.

**REID, THOMAS, M.D., F.F.P.S.Glas.,** has been appointed Ophthalmic Surgeon to the Sick Children's Hospital, Glasgow.

**RENTON, J. CRAWFORD, M.B., L.R.C.P.Ed., L.R.C.S.Ed., F.F.P.S.Glas.,** has been appointed Dispensary Surgeon to the Western Infirmary, Glasgow.

**RICH, A. CRESWELL, M.B.Lond., M.R.C.S.,** has been appointed Pathologist to the Liverpool Royal Infirmary, vice F. T. Paul, resigned.

**SEMPLE, ANDREW, M.B., C.M.,** has been appointed House-Physician to the Royal Infirmary, Glasgow.

**STEWART, CHARLES W., M.A., M.B., C.M.,** has been appointed House-Physician to the Royal Infirmary, Glasgow.

**TUDOR, JOHN, M.R.C.S., L.S.A.Lond.,** has been appointed Consulting Surgeon to the Dorset County Hospital.

**WILLCOCKS, FREDERICK, M.D.Lond., M.R.C.P. & M.R.C.S.,** has been appointed Assistant-Physician to Charing-cross Hospital.

**WILSON, JAMES L., M.B., C.M.,** has been appointed House-Physician to the Royal Infirmary, Glasgow.

**WILSON, WILLIAM MACKNIGHT, M.B., C.M.,** has been appointed House-Surgeon to the Royal Infirmary, Glasgow.

**YOUNG, CHARLES STEWART, L.F.P.S.Glas., L.S.A.Lond.,** has been appointed Assistant Medical Officer to the Barnhill Hospital, Glasgow, vice Dr. Taylor, resigned.

## Births, Marriages, and Deaths.

### BIRTHS.

**GANGE.**—On the 9th inst., at Court-street, Faversham, the wife of Frederick A. Gange, M.D., of a son.

**GIBSON.**—On the 4th inst., at Stanley House, Blackstock-road, Finsbury-park, N., the wife of J. C. Gibson, L.R.C.P., L.R.C.S., of a daughter.

**KIDD.**—On the 5th inst., at 60, Brook-street, W., the wife of Percy Kidd, M.B., of a son.

**MACCALL.**—On the 7th inst., at Hope Bank, Kersal, the wife of William McCall, M.D., of a daughter.

**NAISMITH.**—On the 9th inst., at Ayr, N.B., the wife of W. J. Naismith, M.D., C.M.Ed., of a daughter.

**PHILLIPS.**—On the 20th ult., at Cheltenham, Gloucestershire, the wife of A. R. Phillips, L.D.S.R.C.S.E., of a son.

**WYNDOWE.**—On the 12th inst., at Bathaston Lodge, Bath, the wife of S. Jardine Wyndowe, M.D., Deputy Surgeon-General (retired), of a daughter.

### MARRIAGES.

**ALLT-NEVE.**—On the 8th inst., at St. Botolph's Church, Aldersgate, by the Rev. Alfred R. Clemens, Nathaniel William Allt, L.K.Q.C.P., Surgeon, of Poplar-place, Wittersham, Kent, eldest surviving son of Terence Allt, Esq., Rathmines, Dublin, to Catherine Fanny, eldest daughter of T. R. Neve, Wittersham.

**BENTHAM-SHARP.**—On the 2nd inst., at St. John's Cathedral, Hong Kong, Robert Bentham, Surgeon, R.N., son of R. Bentham, M.D., of London, to Ellen Lydia, daughter of the late F. Sharp, of Norwich.

**POUNDS-LEWIS.**—On the 30th Oct., at St. Saviour's, South Hampstead, T. Henderson Pounds, M.R.C.S., L.S.A.Lond., eldest son of Capt. Pounds, R.N., to Katharine, eldest daughter of James Lewis, R.N., of Adelaide-road, N.W.

**WARD-TUKE.**—On the 13th inst., at St. Mary's Cathedral, Edinburgh, Alfred Ward, M.B., of Anston, co. York, youngest son of William Sykes Ward, of Denison Hall, Leeds, to Emily Elizabeth, only daughter of John Batty Tuke, M.D., F.R.C.P.E., Charlotte-square, Edinburgh.

**WYLIE-CLARKE.**—On the 7th inst., at Christ Church, Skipton, William Wylie, M.D., L.R.C.P.Ed., of Skipton, eldest son of the late E. Wylie, Esq., of Fourtowns, co. Down, to Edith Jane, youngest daughter of the Rev. W. H. Clarke, M.A., Vicar of Christ Church, Skipton.

### DEATHS.

**ASKHAM.**—On the 9th inst., at Clovelly House, Woking Station, Surrey, Henry Francis Askham, M.R.C.S., late Medical Officer of Her Majesty's Convict Prison, Portland, and formerly of Dartmoor and Woking Prisons, aged 47.

**BRICKWELL.**—On the 9th inst., at Somersham, Hunts, Henry Brickwell, M.R.C.S., L.S.A.Lond., aged 65.

**CROFT.**—On the 10th inst., at Bicester, at the residence of his father-in-law, Jonas Paxton, John Henry Croft, M.R.C.S., L.S.A.Lond., aged 42.

**DE GRAVE.**—On the 13th inst., at the residence of his nephew, Edward Perronet Sells, Morland-road, Croydon, John Francis De Grave, M.D., M.R.C.P.Lond., M.R.C.S., Past Master of the Society of Apothecaries, in his 92nd year.

**GOULD.**—On the 15th inst., at 16, Queen Anne-street, London, Katie, the dearly-loved wife of Alfred Pearce Gould, F.R.C.S.Eng., aged 27.

**KINGSTON.**—On the 11th inst., at Church Lawford Rectory, Warwickshire, Peter Nugent Kingston, M.D., late Consulting Physician at Westminster Hospital, aged 77.

**NOOTT.**—On the 4th inst., at Quay-street, Cardigan, Henry Curtis Noott, L.R.C.P.Ed., M.R.C.S., aged 33.

*N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

## Notes, Short Comments, and Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."

## DR. DOBELL'S CHANGE OF ADDRESS.

A LARGE correspondence, for which we cannot find room, has reached us on this subject, including a letter from Dr. Dobell himself, to the effect that the profession is a brotherhood, and that the intimation of a change of address by one of its members is to be regarded as an act of social courtesy and a means of preventing inconvenience to patients and their advisers. The objection to it, of course, is that it is liable to great abuse, and to be done in an advertising sort of way. When done by consultants it ought to be strictly limited to professional brethren in the habit of consulting them. The feeling with which Dr. Dobell's card has been received is probably to be explained chiefly by the circumstances that it has been distributed on a very wholesale scale, and to many who were not in the habit of consulting him, and who had not even the pleasure of knowing him. The intimation of a change of address, if restricted severely to those who have a right to be informed, is never resented; where it is resented there must be some deeper explanation.

Mr. C. P. Chittenden will see that we have treated of one of the subjects of his letter elsewhere.

Mr. Jessop (Leeds).—Mr. Barraud, Oxford-street, London, W.

## LACTRINE.

To the Editor of THE LANCET.

SIR,—As you have recently handled scientifically the subject of the medium through which the rays of the electric light should pass so as not to injure the eyesight or produce painful sensations, I venture to ask your attention to a new variety of glass, which softens the electric light without diminishing its luminant quantity. This glass is termed "lactrine," and it resembles, almost in the degree of facsimile, the opal gem, being less cloudy and absorbent than the common opal glass, and of a finer and purer quality. A perfect specimen of "lactrine" glass may be viewed in the shop of Messrs. Wolff, tailors, London-bridge, having been recently placed there by the Metropolitan Brush Company. Contrasted with the alabastrine glass, adopted for the most part by the electric companies, this shows to the greatest advantage, and that it has met with favour among electricians, I augur from the fact of its being now exclusively used by the Hammond Company, and this, too, both for arc-lights and for incandescents. Lactrine can be tinted if desired, and as an article of manufacture its prime cost exceeds that of alabastrine by the merest trifle, while it does not require the eye of a connoisseur to decide which of the two is the more artistic and effective, as well as the better protector of the eye.—I am, Sir, yours, faithfully,

The Lactrine Syndicate, 151, Cannon-street, E.C.

Nov. 13th, 1882.

C. READE.

## CHLORATE OF SODIUM IN STOMATITIS.

To the Editor of THE LANCET.

SIR,—In the concluding paragraph of a paper by Drs. Ringer and Salmon, on "the Action of the Salts of Sodium, Ammonium, and Potassium," appearing in your issue of Nov. 4th, the value of chlorate of sodium in ulcerated conditions of the mouth is pointed out. May we crave a few lines to say that its application in this way is not altogether new, as for the last three years we have made chlorate of sodium pastilles, forming one of a series of medicated throat pastilles which we originally prepared at the suggestion of Dr. Prosser James, and which have been exhibited at the Cambridge and other meetings of the British Medical Association and elsewhere. These pastilles, however, have never been brought before the notice of the profession in the advertisement pages of the medical journals, and are consequently but little known.

We are, Sir, yours faithfully,

Plough-court, Lombard-street Nov. 15th, 1882.

ALLEN &amp; HANBURYS.

## Medical Diary for the ensuing Week.

## Monday, Nov. 20.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10½ A.M. each day, and at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M. each day, and at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPEDIC HOSPITAL.—Operations, 2 P.M.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.; on Tuesday, 9 A.M.

MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Haward will show a Man with Intra-Thoracic Aneurism.—Dr. Frederick Hicks will show Instruments for the Treatment of Intra-Thoracic Abscess.—Dr. Thorowgood, "On the Treatment of Intra-Pleural Effusions."

## Tuesday, Nov. 21.

GUY'S HOSPITAL.—Operations, 1½ P.M., and on Friday at the same hour.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 3 P.M.

PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. The following specimens will be shown:—Fatty Degeneration of Walls of Heart; Microscopical Specimens of a New Disease of Lymphatics; Embolus from the Left Auricle of the Heart; Syphilitic Gumma in Wall of Left Ventricle; Testis in the Perineum with Congenital Hernia; Unusual form of Growth in the Bladder; Rickets in a Baboon.

## Wednesday, Nov. 22.

NATIONAL ORTHOPEDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.

ST. THOMAS'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.

ST. MARY'S HOSPITAL.—Operations, 1½ P.M.

LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

GREAT NORTHERN HOSPITAL.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2½ P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at the same hour.—Skin Department: 1.45 P.M., and on Saturday at 9.15 A.M.

HUNTERIAN SOCIETY.—3 P.M. Mr. Jonathan Hutchinson, "On Certain Diseases allied to Erysipelas."

## Thursday, Nov. 23.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—1½ P.M. Surgical Consultations.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and on Friday at the same hour.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2½ P.M.

HARVEIAN SOCIETY.—Harveian Lectures: Mr. Henry Power, "On Ophthalmic Medicine and Surgery in relation to General Practice."

## Friday, Nov. 24.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1½ P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 2 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.

QUEKETT MICROSCOPICAL CLUB.—3 P.M. Mr. B. W. Priest, "On the Statoblasts of the Fresh-water Sponges."

CLINICAL SOCIETY OF LONDON.—Dr. Cavay, "On Two Cases of Symmetrical Congestive Motting of the Skin" (patients will be shown).—Mr. J. E. Adams, "On a Case of Lumbar Nephrectomy for Carcinoma."—Mr. R. J. Godlee, "On Two Cases of Intussusception in Infants treated by Abdominal Section."—Dr. Dyce Duckworth, "On Two Cases of Subcutaneous Rheumatismal Nodes" (one of the cases will be exhibited).

## Saturday, Nov. 25.

KING'S COLLEGE HOSPITAL.—Operations, 1 P.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

## THE CHOLERA AT MANILLA.

THE following is an extract from a private letter received by a gentleman in Manchester from Manilla, and published in the *Manchester Guardian* :—

"We have had the cholera here in about its worst form, I suppose, since the mortality in Manilla and suburbs alone may be put down at not far from 20,000, or about 10 per cent. of the population. The death-rate got up to 1500 one day, but now, thank God, it has got down to 80 odd, and is diminishing fast. As if this was not calamity enough, we have had a strong typhoon for several days, and last night and this morning two long and nasty earthquakes. It is a sweet country to live in. It has been a perfectly horrible time, worse than the earthquakes of 1880. Trenches have been dug in different places, and the dead buried like carrion. They dug a trench at Santa Luca, and within twenty-four hours had buried 112 bodies in it, three and four deep. We went to the Governor-General about it, and got a stop put to it. These 112 all came from San Miguel. At the Loma there were 762 buried in one day; for a week the death-cart and coffins were going night and day, and the streets were quite deserted. By order, bonfires have been burning in front of every house for more than a fortnight. No men can be got to load lighters or work anywhere. What Chinese or Indians could be caught in the streets were pressed by the veterans into the service of carrying the dead. Provisional hospitals have been opened all round, in which about 90 per cent. of the patients are said to have died."

## UNIVERSITY OF BRUSSELS.

WE do not publish the lists of the new graduates of foreign universities.

## "INUNCTION IN SCARLATINA."

To the Editor of THE LANCET.

SIR,—As this subject is important, and as so little appears to be forthcoming regarding it, I beg space for a few lines. For about a year I have ceased to prescribe inunctions in scarlatina and in pulmonary diseases. Clinical observation is often misleading—*post hoc propter hoc*; but I fancy that I have observed an aggravation of symptoms after rubbing in oil, and I now object to interfere with the respiratory, excretory, and temperature regulating functions of the skin for reasons similar to those anyone would have against coating over the respiratory surface of the lungs, &c. The skin is an organ as well as the liver or the lungs, and is it not true that dyspnoea, anasarca, and fever may be produced in, say, a frog or a rabbit by simply varnishing its skin?—that radiation of heat is lessened from the surface, say, of a liquid by the superimposition of a thin stratum of oil, and that evaporation from such a surface is diminished by the oil? Does not the interference with the action of the skin (plus the disorder of the nervous system) explain the origin of the inflammatory affections of the chest with which we are daily familiar, and the congestions and ulcerations of the duodenum after burns? Does not congestion or inflammation, with exudation and consequent inability of the skin to perform its natural functions, explain scarlatinal dropsy? Why make matters worse by rubbing in oil?

In scarlatina I direct my patients that the whole of the skin be well sponged with a warm, strong solution of borax, which, while it dissolves the epidermis, also, let us assume, renders the virus innocuous, promotes cutaneous respiration and excretion, reduces temperature, and mixes readily with the sudoriferous, and saponifies the sebaceous matters. After the boracic wash the skin is entirely and thoroughly to be moistened with thin glycerine, which promotes an exosmotic current, soothes and relieves the congestion of the skin, and keeps any dry epidermic dust from floating about.

Of a few cases of scarlatina treated on these lines in a small practice I have twice had solitary cases in children of large families in small houses, but in both cases the mothers were diligent and attentive to instructions.

Glasgow, Nov. 9th, 1882.

I am, Sir, yours, &c., ROBERT WALLACE.

To the Editor of THE LANCET.

SIR,—An observation on inunction in scarlet fever may be interesting to some of your readers. I find inunction is never beneficial to the skin in scarlet fever or any eruptive fever, for any oily substance rubbed into the whole or greater part of the skin clogs its pores and checks its action at once, throwing additional work on the already overworked kidneys, the kidneys being invariably overtaxed in eruptive fever with high temperature. If the skin is left alone, I find it is very seldom that kidney trouble or anasarca follows, and if careful precautions be taken, by the poor as well as rich, the disease will seldom spread.

Chlorine gas, formed by sprinkling vinegar and water upon chloride of lime, makes one of our best disinfectants, and should be plentifully supplied in the infected house.

I am, Sir, your obedient servant,

Sackville-street, Nov. 13th, 1882.

JAMES STARTIN.

Mr. Thomas Smith.—We think the "nineteen bottles of lotion at 2s. 6d. each" a weak part of this case, calculated to produce a bad impression on a judge.

Mr. Turner (Norwich).—Yes, if very brief.

## SINGLETON'S OINTMENT.

To the Editor of THE LANCET.

SIR,—Will you or any of your readers kindly tell me what Singleton's golden eye-ointment is composed of?—I am, Sir, yours truly,  
November 15th, 1882.

RUSTICUS.

## EXAMINATIONS AT THE ROYAL COLLEGE OF SURGEONS.

THE first Primary Examination for the present session for the Membership of the College was commenced on the 8th instant, when ninety candidates presented themselves, against ninety-one at the corresponding period last year. The following were the questions on Anatomy and Physiology submitted on the present occasion, when the candidates were required to answer four, and not more than that number, out of the six questions, from 1 o'clock until 3 for Anatomy, and from 4 to 6 for Physiology :—

## Anatomy.

1. The skull-cap and the subjacent dura mater having been removed, describe the manner in which you would proceed to take out the brain from the cranial cavity.
2. Describe the course and relations of the inferior vena cava; and enumerate the veins which it directly receives, in their order from below upwards.
3. Describe the ligaments which connect the os calcis with other bones.
4. Describe the external anatomy and relations of the kidney. What appearance does it present on section to the naked eye?
5. Give the dissection necessary to expose the superior profunda artery and its anastomoses.
6. Name the nerves of the larynx, and describe their origin, course, and distribution.

## Physiology.

1. Describe the structure and mode of growth of a long bone.
2. Describe the movement of the blood in the capillaries as seen with the microscope; and explain the chief phenomena which can thus be observed.
3. Explain the manner in which ordinary inspiration and expiration are accomplished.
4. Give the functions of the anterior and posterior roots of the spinal nerves, and the evidence on which your statements rest.
5. Explain the terms syncope, apnoea, dyspnoea, asphyxia. How is death produced by asphyxia?
6. What is the composition of milk? Describe the digestion and absorption of its organic constituents.

T. J. H.—The instructions are good and well stated. The initials had better be deleted.

## ON TRANSFUSION.

To the Editor of THE LANCET.

SIR,—In a paper on the above subject in to-day's issue of THE LANCET, Mr. Le Page writes: "My special intention is that of supplying the obstetrician with a safe and facile means of transfusing blood after post-partum hæmorrhage, where the diastolic system is practically dead, and the heart is dynamically incapable of action in consequence of the absence of fluid to act upon."

Are the means he supplies us with both "facile and safe?" I cannot conceive that it is a very facile matter, alone and unassisted, to retain both cannule in the veins of the donor and receiver of blood, with one hand, whilst "pressing the ball and releasing the lever" with the other, supposing the operator to have overcome the initial difficulties of opening the two veins and introducing the two cannule. The "diverticulum" to arrest the air bubbles, if any be left, in the tubing is ingenious, but surely it may be a source of some trouble in that, in filling the apparatus with the soda solution, it will want some dexterity to empty the branch of the air it originally contained. Again, the diverticulum will be useless as far as arresting air is concerned, unless it can be kept upright, or nearly so, throughout the operation. A serious objection to it is that it would undoubtedly be a focus for coagulation.

Mr. Le Page claims that his instrument measures the quantity of fluid transmitted. Well, so does Aveling's. The mere quantity as expressed in drachms and ounces of the blood or saline fluid introduced into the receiver's vein is not to the point. The operator stops when the patient rallies, or if he be transfusing, when he finds the donor has given as much as it is safe to lose. It is impossible to predict that the receiver requires so many ounces, or that the donor can give so much.

Mr. Jennings very clearly pointed out (THE LANCET, Sept. 16th and Sept. 23rd, 1882) that the many objections inherent in blood-transfusion, especially in the immediate method, practically disqualifies it for those cases which the accoucheur and the general practitioner most frequently have to face unexpectedly and without any assistance. I fall to see that Mr. Le Page has removed any of these objections; on the other hand, he has introduced to us a complex modification of Aveling's instrument.

All the dynamic effect required for the circulatory system is supplied in the saline-alcoholic fluid of Little (which in this class of cases is the sole effect which is desired), without one tithe of the risks or difficulties of the immediate method of transfusion. The supply, further, is unlimited and always accessible.

It would be interesting to know whether Mr. Le Page has ever used his apparatus in actual practice. The value of the intravenous injection of the saline-alcoholic fluid has been lately exemplified by the case published in THE LANCET on Sept. 16th, 1882, and within the last twenty-four hours it has come to my knowledge that this method has again been carried out with success in another case, at the London Hospital, by means of Jennings's "syphon," the notes of which I hope will appear in due course.

I am, Sir, yours faithfully,

Duke-street, Manchester-square, W.,  
Nov. 11th, 1882.

W. H. FENTON-JONES.

## TESTS FOR COFFEE ADULTERATION.

a work now in course of publication at Breslau, Professor Wittstein gives details of the tests which he regards as effective in the discovery of false colouring on coffee, such a process being, it is explained, resorted to in order to give to inferior and sea-damaged kinds the appearance of superior descriptions. To detect the presence of lead he recommends the placing of the suspected coffee-beans in diluted nitric acid (of 1.10 specific gravity), which is poured off after one hour, and further diluted with three times its bulk of water. By the addition of sulphide of hydrogen the lead is made to form a black precipitate. Another mode of colouring coffee-beans is said to be by the use of a greenish powder, composed of Prussian blue, chromate of lead, clay, and gypsum. In order to discover the presence of this colouring matter, warm distilled water is poured over a quantity of the coffee-beans. After a couple of hours they are taken out again, and the water is allowed to become clear. If gypsum has been used, the water is rendered turbid by chloride of barium. If Prussian blue has been used, it can be readily traced by applying potash-lye, which immediately changes its colour into brown. If this change does not take place, it may be inferred that indigo has been used instead of Prussian blue, and in that case nitric acid will destroy the colour. During the treatment with potash-lye the chromate of lead is more or less affected, and is partially or wholly dissolved; while if turmeric has been used, it only takes a brown colour. As a further test, hydro-sulphuret of ammonia is spoken of as being able to show the presence of chromate of lead if any blackening takes place.

## REGISTRATION OF STILL-BIRTHS.

r. A. J. Newman.—Our correspondent is under a misapprehension in believing that recent legislation has provided for the compulsory registration of still-births. No entries relating to still-births are made in the national register either of births or of deaths. The Births and Deaths Registration Act of 1874, sec. 40, provides that any person who "wilfully makes, gives, or uses any false statement or representation as to a child born alive having been still-born, or as to the body of a deceased person or a still-born child in any coffin, or falsely pretends that any child born alive was still-born, or makes any false statement with intent to have the same entered in any register of births or deaths, shall for each offence be liable, on summary conviction, to a penalty not exceeding £10, and on conviction on indictment to fine or imprisonment, with or without hard labour, for a term not exceeding two years, or to penal servitude not exceeding seven years."

ndymion.—There is no single work dealing with the principles of preventive medicine, and the information must be gathered from a series of works. As text-books, Parkes' work on Hygiene, together with Wilson's Handbook of Hygiene, are perhaps the best. An excellent list of the works in question is appended to the papers given at the Sanitary Science Examination at Cambridge, and published at the Cambridge depot, Paternoster-row, E.C.

## VICARIOUS MENSTRUATION.

To the Editor of THE LANCET.

SIR,—A peculiar case having occurred of the above nature in the district over which I have charge, I venture to inform you concerning it. A single woman, aged twenty-six, came to consult me concerning her right eye, which she says "is very dim, and difficult to see out of, especially at night." Upon the inner canthus, close to the entrance of the superior lacrymal canal, was a small papule. The pupils appeared normal and the eyes natural, though last month the cornea of the right eye appeared congested. She is a bilious subject, and has loss of appetite, and sickness in the morning. The breasts are small, but fairly well developed. The menstrual flow has never been regular, and if any appears it is very slight and colourless. She does not appear to be anæmic, and the heart sounds are healthy, though she complains of sickness and pain in the frontal region, and always in the right eye.

About the middle of August last profuse hemorrhage took place from the papule mentioned, and a colleague says "it spurted out as if from a wounded artery." After a pad of cotton-wool with a bandage had been applied over the part and she had gone home, it commenced again, and another medical man was summoned on the same day (Wednesday), who adopted similar treatment, and the bleeding from the eyelid stopped till Friday, but it came on again on the following Monday, in spite of ice, &c. It first began from the right inner canthus, then it occurred from the left inner canthus, of the eyes; then bleeding from the nose and mouth followed.

As it would appear to be a case of extreme rarity to have hemorrhage in this region "vicarious of menstruation," I have determined to watch the case. I am giving aperients, with ergot and bromide of potassium, and recommend rest and cold applied to the head, as the symptoms threaten to recur. I shall also endeavour to induce normal menstruation from the proper channel as the periods come round. So far my treatment is successful.

I should be glad if any of your readers would inform me of similar cases, and for their opinion concerning this one.—Yours truly,  
G. DE COURCY MORRIS, M.D.

York, Nov. 1882.

## THE POPULATION OF CANADA.

THE above question has been receiving attention in the continental press, with special reference to the difference in the rate of increase of the French Canadians as compared with that which is recorded to be the case in France. It is stated that Canada has a French speaking population of about a million and a quarter who are lineally descended from the Norman and Breton colonists, who numbered not quite 11,000, and who emigrated to Canada during the 150 years of French supremacy in that part of America. Since Canada ceased to belong to France there has been practically no emigration from that country; in fact, there has been a somewhat extensive emigration of French Canadians from Canada to the United States. The French colonists have increased in number from 1,032,000 ten years ago to the present population of 1,238,929 souls, being an augmentation of about 20 per cent.

## CELLULOID TRACHEOTOMY TUBES.

To the Editor of THE LANCET.

SIR,—Will you allow me to add my testimony to that of Mr. Green, in your last issue, as to the value of the above. About eight months ago Messrs. Mayer and Meltzer made me one, and I used it in May for a child on whom I performed tracheotomy for diphtheria. It answered the purpose very well indeed, and I have frequently used it since. Being probably the first tube of that material ever made or used, it did not quite meet all the requirements I look for in a tracheotomy tube. In such a case as Mr. Green's it is *par excellence* the tube to use, and the property it possesses of being moulded is an additional advantage. Moreover, in such a case no inner tube is required; but in cases of tracheotomy where there is much expectoration of mucus or membrane an inner tube is generally necessary. In my tube the inner did not glide easily within the outer tube, and was withdrawn with great difficulty, but such a defect is no doubt easily obviated.

After a fairly large experience in tracheotomy, I think the tubes advocated and used by Mr. R. W. Parker by far the best in the largest number of cases. In them the inner tube glides easily within the outer, and is as easily retained; the curve corresponds to the natural curve of the trachea, and it has the collar movement. I am having one of these tubes made in celluloid with such modifications as the nature of the material demands. The difficulty is to get tubes of the largest possible calibre with a maximum of strength and a minimum of general bulk.

I am, Sir, yours faithfully,

J. SCOTT BATTAMS,  
Resident Medical Officer, East London Hospital  
for Children.

Nov. 12th, 1882.

Hypatia.—There is no law to prevent obstetric practice by anyone. The chances are that if such an individual be allowed latitude enough he will come to grief. The address in question is Mr. Carpenter, 130, Stockwell-road, London, S.W.

## HOME FOR INVALID LADIES OF LIMITED MEANS.

To the Editor of THE LANCET.

SIR,—We have been requested to draw the attention of your readers to the present opportunity of filling some vacancies in the home for invalid ladies of limited means, which has been established here for the past four years. The object of this institution is to extend the advantages of one or two winters' residence in this climate to such ladies of limited means as may have a fair prospect of recovery and return to an active part in life, and it is thought that the profession will be glad to know of this institution, and will best bring it to the knowledge of those for whom it is intended.

We remain, Sir, yours faithfully,

A. J. FREEMAN, M.D., Medical Officers to the Home  
L. E. KAY SHUTTLEWORTH, J. for Invalid Ladies.

San Remo, Italy, Nov. 8th, 1882.

S. H. J. should consult our article in the Students' Number, published on Sept. 9th last.

Herrn Breikoff and Hartel (Leipzig).—We cannot exchange.

## POOR-LAW MEDICAL SERVICE AND BOARDS OF GUARDIANS.

To the Editor of THE LANCET.

SIR,—Assistant medical officers under the Poor-law system it appears may be dismissed by Boards of Guardians without the consent of the Local Government Board, they falling under the Consolidated Order 183. Such medical officers should insist on a certain amount of notice when they are first engaged, for, with the above powers, nothing prevents them from only getting twenty-four hours' notice of dismissal. In my case a month's notice was given me, with which I was not satisfied, and refused to accept it. However, the Local Government Board have written and said the guardians have the power so to act. Thinking this information may be of use for future candidates for similar offices, I have taken the liberty of sending it to you.

I remain, Sir, yours, &c.,

ASSISTANT RESIDENT MEDICAL OFFICER,

Nov. 14th, 1882.

## Inaugural Address

DELIVERED AT THE

GLASGOW INFIRMARY MEDICAL SCHOOL,

On November 1st, 1882.

By EBEN. WATSON, M.D., F.F.P.S. GLAS.,

SURGEON AND LECTURER ON CLINICAL SURGERY AT THE INFIRMARY.

MY LORD PROVOST AND GENTLEMEN,—I consider it an honour to be asked to take part in the interesting proceedings of this day. I congratulate you all—teachers and students alike—on your taking possession of the admirable building in which we are now met as the future home of the Glasgow Infirmary School of Medicine. I have in my time visited several such schools in this country and on the continent, and I will say that I have not seen any one better, if so well, adapted to the purposes of medical teaching. The lecture-rooms are well lighted, well aired, and suitably seated to give all a good view of the lecturer's table, while the laboratories are convenient, and well fitted up with the necessary appliances for work. On the whole, I feel sure that if my friends the lecturers have not ample audiences to listen to their prelections, and if you students do not make good and satisfactory progress in your studies, will not be the fault of the architectural arrangements or your comfort, or the educational requirements at your command.

Yours is comparatively a young school, and has much of its reputation still to make, and therefore I think it is a matter of no small congratulation to you that you have such a close connexion with one of the oldest and best schools of medicine and surgery in the West of Scotland—I had almost said anywhere to be found—I mean the Royal Infirmary. You share its name, and to some extent its high prestige, and situated as your building is you almost seem to form part of it. Yet here, in passing, I cannot but express the hope that the day is far distant when the management of the infirmary will depart from that catholicity which has hitherto characterised it, and when that institution shall become in any degree less of a common platform on which the teachers and the students of all schools may meet on terms of perfect equality, and be dealt with in a spirit of thorough impartiality. I am sure I may take it for granted that none of you would wish for such a change. You are willing to stand, as a school, on your own merits, and one of the chief of these must ever be the advantage you are able to take of that older institution which has been doing such good service in the past.

I believe it is eighty-eight years since our infirmary first opened its wards for the reception of the sick and wounded poor, and it is pleasant to let one's imagination wander over that long period and lose itself in the attempt to estimate the amount of good it has done, not only to the immediate objects of the charity, but also through the medium of the many generations of physicians and surgeons who have owed to it their training and their skill. Then there is another aspect in which we may well be proud of our infirmary, for it has amply borne its part in contributing to the advancement of the healing art. Much in this respect has been done indirectly, as I may say, by those who after studying here have gone far away from our city, but much has also been done directly and immediately in the very wards of the infirmary. I feel that I cannot and ought not to enter here into details of this subject, yet I may be allowed to give two examples of what I have now said. There has lately departed from among us a veteran in surgery—Dr. Andrew Buchanan—whose ingenuity, guided and called forth by his experience at our infirmary, has afforded us several new procedures, and specially one great operation which will make his name long remembered with esteem. Then you doubtless know that it was in the wards of the Royal Infirmary that Mr. Lister was led to make that application of Pasteur's discovery to the healing of wounds which has resulted in the antiseptic system of surgery—a system which has revolutionised the art, and now enables us to perform with safety operations at

which the boldest surgeons of former times would have stood aghast.

Now I have thus, in few words, brought before you the high and established reputation of the Glasgow Royal Infirmary as a field of medical and surgical training, not to boast of it, but for the purpose of urging upon you that your best policy is to make your character as a school mainly rest on its practical nature. Surely this is to be expected of a hospital school, and I think it will best recommend you to all concerned, to the authorities who legislate on medical education, as well as to the students who may fill your halls.

Some time ago medical education in this country, especially in England, was too practical. The young aspirant to our profession was sent as an apprentice to some general practitioner, and he was taught to make pills and potions, and by-and-by to visit patients, and only after this course of instruction was he sent to school or college to pick up what science he could. After that period came a reaction, and then the only desideratum appeared to be science, and not practice. It was to be taught by specialists, and studied without reference to its application. Natural history, botany, and chemistry, even anatomy and physiology, were to be studied by the perplexed and overburdened student as pure sciences for their own sakes. The idea of medical chemistry, of surgical anatomy, or of physiology, as the institutes of medicine, was scouted as far beneath the requirements of the day. But somehow it has been discovered that there is a mistake in all this; that such an education might make scientists, but would never make practitioners of medicine; and hence another reaction is, I think, now taking place, and I hope it will not be carried too far, in favour of more practice for our students, even if they learn less science. In proof of this you find THE LANCET, which is a very good index of opinion in our profession, enunciating the dictum that medical students of the present day are "under-educated and over-examined."

For my part, I would rather say that they are often not well—not quite rightly—educated. They are over-educated, if you like, in some things; and much under-educated in other things. Take physiology, for example, with the teaching of which I am very familiar. Is it not the fact that the time and the energies of the student are often wasted on what to him are trifles, while the great and important truths which are to regulate his practice are slurred over in so superficial a way that he is apt to lose sight of them altogether, and really not to know much about them? Some years ago I visited the physiological laboratory of a distinguished university at a considerable distance from Glasgow, and it so happened that some students were sitting at the table when I was shown round by their professor. He explained to me that they were answering the written questions for one of their degree examinations; and what do you think was the nature of the questions over which the perplexed students were cudgelling their brains? Were they about the functions of the kidney, or the liver, or the lungs, or any other important organ of the body? No. The students were required to describe certain very pretty physiological instruments, fine balances, sphygmographs, recording drums, &c., which were all placed before them on the table under their appropriate glass cases. I hope that did not form the whole of their examination in physiology; but the fact of this being such a remarkable part of it showed that in the lecture-room far too much importance had been put upon the methods of physiological investigations, while the results, the facts of physiology as applicable to practice, must have been proportionately less insisted on and drilled into the students' minds. The same thing might likewise be said of what are called the practical branches of the curriculum, though in my opinion all your studies ought to be practical from anatomy onwards. Suppose surgery, for example, to be taught apart from actual practice on living men and women, and anyone can see how useless it would be. The fine-spun theories of the lecturer may be plausible enough as he puts them, and the cases which he relates of course all turn out successfully, but one grain of demonstration in the wards of a hospital on the living subject must be acknowledged to be worth bushels of such oratory. The conclusion, then, to which we are necessarily driven is that lectures may be and ought to be the best preparatives, but are only preparatives, for work in the wards of the hospital; and I augur well for this school inasmuch as I hope and believe that the sentiments I have now expressed accord pretty nearly with those of your teachers, and that

x

they will endeavour as soon and as constantly as they can to refer you to what they will excuse me for calling the best part of their teaching—viz., that which they show you in the infirmary.

With the other part of THE LANCET's dictum we have not so much to do here; but I have no objection to state it as my opinion that students are over-examined, because too much is required of them at that early stage of their history, and because their examiners are too often specialists in their branch who are apt to forget how defective was their own early knowledge, and also how little they know of the other subjects, on all of which the student is expected to be well informed. Surely too much is required of our students, regarded *en masse*. The bulk of them are destined to be general practitioners, and not operating surgeons or consulting physicians, and I think that the true remedy for much of the complaint now made, both of over-examining and with still better reason of unequal and uncertain examining, lies in the institution of a single board of experienced examiners, not being teachers, for each country, and a minimum qualification essential for all, but not essentially the only one for all. I say, let there be one qualification sufficient, but not more than sufficient, for a licence to practise, and let those who can and wish it add to that qualification other and higher qualifications, according to their circumstances and prospects in after-life.

But, as I must now draw these necessarily brief remarks to a conclusion, I wish, for the few minutes longer of your time which I can occupy, to urge still more specially upon you students to take fuller advantage than some of you do of the great hospital which is so near you now. Afterwards you may enjoy no such opportunities, and in your possibly distant practices you may often long in vain for another look into the wards to see how this or that case is managed there. My advice to you in plain words is, that you should seek for dresserships early in your career, so that you may have the right and be almost forced to come into actual contact with the patients. The more and the earlier you work with them the better will you be fitted for your future duties. You may not fully understand all that is said or done in the wards at first, but taken along with the instructions you receive in your classes, it is strange how quickly the required knowledge will come to you if you put your heart into your work. "Nulla dies sine linea" is a good old maxim, which in your case may be taken to mean, Let no day pass without its lesson learnt, its fact stored up in your memory. Then by the end of your sojourn here your minds will be filled with practical knowledge, and your heads and hands accustomed to bring that knowledge to bear on your patient's circumstances.

To stimulate your zeal I would remind you that the character and success of this school depend greatly on you. Your character and behaviour now will be regarded, and rightly regarded, as the index of the character which your school ought to bear; while your success hereafter will be its best recommendation to others. In short, I wish to more than hint at a qualification not often spoken of by lecturers, but which is almost as necessary for success in practice as a good knowledge of your profession—I mean quiet and gentlemanly manners, and a something in your style indicating kindly interest in all who consult you.

If you enter the graveyard of our cathedral and turn a little to the right you will come to the tombstone of Dr. Peter Low, the distinguished founder of the Faculty of Physicians and Surgeons of this city, and you will read in his quaint epitaph some such words as these—

"Though his physis sometimes failed,  
His pleasant humour aye prevailed."

I wish we could all have such a pleasant humour. Try to have it as yours from the first, and then your recollections of this happy student-time which you are now enjoying will be unclouded with regret; and in your future lives, if cares must come, they will be less bitterly felt by you because they will be shared, in sympathy, by others whom you have assisted and comforted in their troubles.

SOME of the leading settlers at Tikorangi, New Zealand, have published a testimonial to the zeal, skill, and kindness of Dr. J. Murray Gibbs in combating an epidemic of diphtheria with which the colony has been lately visited. Such an expression of gratitude is honourable alike to doctor and patients.

## ABSTRACT OF

## Lecture

ON THE

## EVOLUTION OF THE STETHOSCOPE.

By SAMUEL WILKS, M.D., F.R.S.,

PHYSICIAN AND LECTURER ON MEDICINE, GUY'S HOSPITAL.

INSTEAD of placing on the table every imaginary form of stethoscope manufactured out of every possible material gathered from the shops of the instrument makers, I will carry you back to the origin of the stethoscope, and you will see how, on the principle of selection and the survival of the fittest the primitive instruments have departed from the scene and are now only to be found amongst the fossilised curiosities, the relics of former ages, on the antiquated shelves of some very old medical practitioner. The stethoscope, as you know, was invented by Laennec. He relates how in the year 1816 he happened to recollect a well-known fact in acoustics of solid bodies conveying sound, and he goes on to say: "Immediately on this suggestion I rolled a quire of paper into a kind of cylinder and applied one end of it to the region of the heart and the other to my ear, and was not a little surprised and pleased to find that I could thereby perceive the action of the heart in a manner much more clear than by the application of the ear." "The first instrument which I used was a cylinder of paper formed of three quires completely rolled together and kept in shape by paste." Laennec then goes on to describe how he copied this roll of paper in wood, metals, glass and other substances, and finally he says: "In consequence of these various experiments I now employ a cylinder of wood an inch and a half in diameter and a foot long, perforated longitudinally by a bore three lines wide and hollowed out into a funnel shape to the depth of an inch and a half at one of its extremities. It is divided into two portions, partly for the convenience of carriage and partly to permit its being used of half the usual length. The instrument in this form—that is, with the funnel-shaped extremity—is used in exploring the respiration and rattle; when applied to the exploration of the heart and the voice it is converted into a simple tube with thick sides, by inserting into its excavated extremity a stopper or plug traversed by a small aperture and accurately adjusted to the excavation. This instrument I have denominated the *stethoscope*."

Fig. 1 represents Laennec's roll of paper, and Figs 2 and 3 the copy of this in wood as he describes. The latter figure

is drawn from an instrument kindly given me by Dr. Galton, of Norwood, being the stethoscope long used by his father. It does not separate into two pieces, but contains the plug which can be removed so as to leave the end hollow. Fig. 4 is the same instrument with the sides cut out to make it lighter and more elegant, the ear piece being the same as before and the mouth also hollowed out. This was the stethoscope used and recommended by the late Dr. Hughes. By making the instrument still more elegant and slender we have the modern stethoscope in endless variety, as in Fig. 5. It is thus very evident how the modern instrument has been framed out of the original block of wood which was made the counterpart of Laennec's roll of paper.

I know not who invented the instruments with flexible

tubes, but I have no doubt that a search into medical history could tell us. I remember, however, that the first flexible stethoscope which I ever saw was the one depicted in Fig. 6, and used by Dr. Golding Bird when he saw out-patients in the year 1843. Being much crippled with rheumatism, and therefore not wishing to rise from his chair, he found this instrument very convenient; he also was enabled to pass the ear-piece to gentlemen standing near him, whilst he held the cup on the part to be examined. I always thought it was his own invention. But, whether so or not, I do not think any great effort of genius was required to frame a flexible instrument, and then adapt it for the use of one or two ears. This being done, the next step would be to make two mouth-pieces to apply to the chest at different spots. Various modifications of these instruments have been made of late years, but the first notice of them I have any knowledge of in my reading is to be found in a letter to THE LANCET of Aug. 29th, 1829, by Mr. Comins of Edinburgh, headed "A Flexible Stethoscope." This was only twelve years after Leannec's invention. It is difficult from his description to picture the instrument, but it seems to have been composed

FIG. 6.

FIG. 7.

FIG. 8.

of jointed tubes, and made for two ears as well as one. Mr. Comins expresses his surprise that the discoverer of mediate auscultation did not suggest a flexible instrument, as he says "it can be used in the highest ranks of society without offending fastidious delicacy."

A very interesting fact was first pointed out to me by Dr. Andrew Clark, with respect to a peculiarity of the binaural in the objective appreciation of sounds; that if each ear piece be separately used, and any sound be made near the mouth-piece, it is heard in the ear itself, but if the two pieces are employed together the sound is heard at the spot where it is produced. The fact is very interesting in a physiological point of view, and further corroborates the theory as to the value of a double set of senses, or, in a word, of the body being made up of two halves, for just as the two hands feeling different parts of an object gain an idea of extension, and the two eyes by obtaining different views of any substance get a knowledge of its solidity, so in the same way the two ears listening to the same sound more thoroughly appreciate its objectivity.

If you look at this series of drawings you may perceive but little resemblance between the first figure and the last, but take them one by one and you will see that the figures are really progressive. My story of development is not imaginary, but historical.

**ABERDEEN MEDICO-CHIRURGICAL SOCIETY.**—At the annual meeting of the Aberdeen Medico-Chirurgical Society, held on Thursday evening, the following office-bearers were elected for the year:—President, Dr. John Urquhart; secretary and treasurer, Dr. James Rodger; librarian, William Fraser, surgeon; council, Drs. Beveridge, Garden, W. J. Simpson, Crombie, William Fraser; representatives to the North of Scotland Medical Association, president and secretary *ex officio*; Dr. Garden and Dr. J. C. O. Will elected.

## NOTES ON CONCUSSION OF THE SPINAL CORD AND BRAIN.

By WM. SCOVELL SAVORY, F.R.S.,  
SURGEON TO ST. BARTHOLOMEW'S HOSPITAL.

Is the current view of the immediate cause of the paralysis which follows a severe injury, as a fracture, of some portion of the spine, correct one? Can the loss, not only of voluntary motion and sensation, but also of excito-motor reflex power in the part below, which is the usual effect, be directly due to pressure on some limited portion of the cord by the fractured bone? In experiments on animals, when the spinal cord is divided at any point, after the shock of the operation has passed off—and this is significant,—the power of reflex action in the part below, as everyone knows, remains. Why, then, is it abolished after fracture? Is it not that the violence which is sufficient to produce fracture is severe enough to produce such concussion or disturbance of the cord below as to destroy its power as a nerve centre? Instead of the common statement that the loss of reflex function is due to pressure at a particular part, would it not be more correct to say that the loss of reflex power below is the result of violence which at the part where it was directly applied was sufficient to break and displace the bone, but which has also injured the cord beyond? At all events, if the loss of reflex function be due to the fracture, it must be indirectly; to some mischief by displacement or dragging inflicted along the cord, of course far beyond the part directly implicated in the fracture; but, at least in many cases, the evidence strongly points to concussion as the cause. In a few exceptional cases, although compression of the cord by the displacement of the fractured bones continues, the portion below recovers its function as an independent centre, for the power of reflex action in the lower limbs is, after a while, restored. The extension and persistence of mischief beyond the seat of visible injury surely claim more consideration than they have hitherto received. But in any case it is not clear why the part above does not to a greater extent lose its reflex power. One would imagine, I think, that the effect of such injury would usually extend almost equally, as indeed it occasionally does, in both directions. How is the clinical fact to be explained?

The curious fact that in concussion of the brain not only may there be complete loss of consciousness for a considerable period after the injury, but that in some cases after complete recovery there may be total loss of memory of all events which have happened shortly before the injury, has not perhaps received the attention it deserves. The following cases may be taken as examples.

The driver of a hansom cab was knocked off his box by an omnibus at the top of Newgate-street, and brought to the hospital in a state of complete unconsciousness from concussion. From this he speedily recovered; but, at least for several weeks after, when he appeared to be in every respect quite well, he could not in the slightest degree recollect what he had done or seen, or where he had been in the half hour immediately before the accident. It was known that within that time he had taken up a passenger at Cornhill, and driven along Cheapside and Newgate-street, yet of this he never had the faintest recollection; but for all events up to this time his memory was excellent.

Again, a gentleman was thrown from his pony at polo, and picked up quite unconscious, in a state of concussion. He recovered from this in the course of two or three hours, and in a few days was as well as ever. But he could never recollect some striking events in the game which occurred within half an hour or so of the accident; yet up to this blank period his memory was minute and accurate.

Now, what happens in such a case? I suppose no one can tell. The substance of the brain is shaken, and presumably for a time damaged in some way or disturbed; or, as we may say, its nutrition is temporarily impaired, and thus may subsequent loss of function be accounted for. The recollection of a bygone event shows that some impression which the brain receives at the time has been registered; and this must be, I suppose, by some change, however subtle, which is more or less durable. Does the violence of the concussion somehow interfere with the registration of

such change; wiping out, as it were, the record before the ink is dry? But such guessing; as this only shows how very far I am from understanding the fact.

## THE PATHOLOGY OF THE BLOOD IN INFLAMMATION.

By JAMES T. R. DAVISON, M.D. EDIN.,

SENIOR HOUSE-SURGEON, ROYAL SOUTHERN HOSPITAL, LIVERPOOL;  
LATE RESIDENT PHYSICIAN, ROYAL INFIRMARY, EDINBURGH.

THE results obtained from the examination of some hundreds of specimens of pathological blood justify me in enunciating, as a pathological law, that "during the active period of inflammation the leucocytes of the blood are increased in numbers." The behaviour of the leucocytes under the inflammatory influence constitutes a most important help towards finding out the existence of inflammatory lesions. I need only mention those cases of obscure internal abscess and the first stages of pneumonia as examples of conditions where occasionally it is next to impossible to recognise them with certainty, and where the examination of the blood may lead us a good way on towards arriving at a certain diagnosis. This alteration of the blood is, for practical purposes, more important than the "hæmatoblastic crisis" described by M. Hayem, for while the latter comes into play at or about the time of the crisis of acute disorders, the former exhibits itself from the very first, even within a few hours from the commencement of the inflammatory process. Thus while the "hæmatoblastic crisis" may for prognostic purposes be interesting, as indicating a favourable course of the disease, it possesses no diagnostic value; but the increase of leucocytes, by indicating the existence of an inflammatory process, and that from the very first, has a great diagnostic value, while it also is an element in prognosis, for the subsidence of the inflammation will be followed by a decrease of leucocytes.

It is well known that the leucocytes are found in greater numbers in the blood during the digestive process. How is this brought about? There is no necessity to assume that this increase is due to a more active formation of leucocytes in the spleen and other blood-forming organs. Recent pathology would favour the view that the increase of leucocytes in the blood is brought about reflexly by increased contraction of the splenic muscle and probably also of the lymphatic muscles, the point of origin of the reflex action being the gastro-intestinal canal. It has long been known that the spleen was capable of muscular contraction, and it has been left to Dr. Roy recently to discover that this contraction is rhythmical in time, and the directions through which nerve force influences this contraction. Dr. Roy believes that the spleen contains a nervous mechanism which regulates its contraction, but he has shown that this contraction is also affected by nerve influence from without—for example, stimulation of the peripheral end of a cut vagus causes contraction of the organ.<sup>1</sup> It is therefore probable that the contraction of the gastric muscle during digestion stimulates the pneumogastrio; that a nerve force is then carried to the medulla oblongata (Dr. Roy showed that stimulation of the vaso-motor centre in the medulla brought about contraction of the spleen), and thence is reflected through the vagi and splanchnics to the spleen, giving rise to increased contraction of its muscle, and thus to a discharge of leucocytes into the circulation. These leucocytes having performed their function, whatever that may be, probably return into the spleen and lymphatic glands, as they are no longer found in excess in the blood after the digestive process is ended.

Once admitting that the spleen can be made to discharge its leucocytes into the blood by a reflex action originating in the gastro-intestinal canal, and knowing the intricate and complicated connexions which exist in the sympathetic system, it will not be difficult to understand that the spleen can likewise be made to contract reflexly by a force originating in the arterioles and capillaries of any part of the body. In the inflammatory area a force—whether it be chemical, resulting from altered nutrition of the tissue cells,

or nervous, reflected from a distant part—paralyses the vaso-motor nerves of the arterioles. Either this same force, or one originating in the walls of the arterioles—the result of distension caused by increase of blood-pressure in the inflammatory area—is carried to the medulla, and thence reflected to the spleen, and thus the spleen is advised that migration of leucocytes is taking place, and a call is made upon it to supply the demand made upon the blood. In inflammation there is therefore a loss of leucocytes from the blood, and an effort of nature to replace them, but, as in the case of hyperpyrexia, nature over-does what is required of it; so here the supply from the spleen and lymphatic glands is greater than the demand, and therefore it is that during the active period of inflammation we find the leucocytes in the blood in such increased numbers.

The simplest form of inflammation that can be selected for examination of the changes in the blood is an abscess, for here there can be no suspicion of other influences being at work other than the inflammatory. If the abscess be acute and large the leucocytes are found in great abundance in the blood; but if the abscess be chronic, although it may be large in size, the leucocytes are not increased to such an extent. In the one case there is an active migration of leucocytes from the capillaries, and a consequent active demand upon the spleen and lymphatic glands; in the other case the migration is passive and small in quantity, and therefore the blood-forming organs are not called upon to supply a large amount of leucocytes. Small abscesses may also give rise to an abundant increase of leucocytes, and at other times to a slight increase only. Probably this difference depends upon the amount of tension and inflammatory fever present. In a case of abscess of the finger which had lasted for nine days, a small quantity of pus being present, but where the patient had passed sleepless nights, I found more leucocytes in the blood than in another case where a chronic abscess containing several ounces of pus had lasted for some months. After abscesses are opened the leucocytes in the blood begin to disappear, but sometimes the defervescence of these cells is interrupted by a secondary increase. When an abscess is opened tension is relieved, and the inflammatory process subdued, and the defervescence which then takes place is in accordance with the principle stated above, the demand for leucocytes being no longer present. The occasional secondary increase of these cells can easily be accounted for by an exacerbation of the inflammatory action. Next in importance to abscesses are scalds and burns, for in these we have an acute inflammation with visible effusion, which develops itself in a very short time, and thus we have an opportunity of examining the blood almost at the commencement of the inflammation. The leucocytes are always increased, and this increase I have noticed as early as two and a half hours from the application of the irritant, clearly proving that the blood-forming organs have acted reflexly and emptied themselves of part of their contents, for in such a short time as two and a half hours the spleen and lymphatics could not have formed all the extra leucocytes found in the blood. In cases of severe scalds and burns the excess of leucocytes may last for a long time, as a pus-secreting surface is left, and hence the migration of leucocytes continues. The same conditions exist in old discharging extensive surfaces, and the same excess of leucocytes is found in the blood. Again, the same principle is manifested in inflammation of serous membranes. In pleurisy the leucocytes may be present in very large numbers, diminishing with the lowering of the temperature. In pleurisy, as in other inflammations, a return of the temperature to normal is not immediately followed by a sudden and rapid decrease of the leucocytes. It is easier for the white corpuscles to enter the circulation than to leave it. Doubtless the lowering of the blood-pressure which takes place at the crisis of an acute inflammation favours the return of the leucocytes from the blood, for the consequent retardation of the peripheral circulation is the nearest physiological approach to pathological stasis, and thus the leucocytes are placed under the best possible circumstances to attach themselves to the capillary walls, and eventually to regain the lymphatic system. Still this cannot take place in a short time, and it is, therefore, that the inflammatory crisis is not immediately followed by a sudden and rapid decrease of the leucocytes. In peritonitis and acute bursitis I found the white corpuscles in excess. In a case of double effusion into the knee-joints four days old, with a temperature of 100·4°, I did not find an increase of the white corpuscles, and here I may state that my ex-

<sup>1</sup> Journal of Physiology, vol. iii., No. 3.

aminations hitherto have been made without the aid of the hæmacytometer, so that what I have observed was what was obvious to any eye educated to estimate the normal amount of leucocytes by glancing over different parts of the field, and thus when the increase of leucocytes was very slight, it would have been unappreciable to the eye; and in this way I must account for the apparent absence of the excess of leucocytes in this case, bearing in mind at the same time that a small migration of leucocytes, apart from tension and inflammatory fever, will call for a small supply from the blood-forming organs, and as the effusion subsided in this case, the amount of white cells it contained must have been small. Somewhat similar to this case are those of chronic synovitis of the knee and hip, and of chronic swelling of rheumatic joints. In all these instances the serous membrane is inflamed, but the inflammation is passive, the migration of leucocytes small, and hence in the blood we find the white corpuscles either normal in quantity or only very slightly increased. In acute rheumatism the white cells are always increased; sometimes the increase is very slight, and sometimes very abundant, and it appears that the greater the number of joints swollen, provided the swelling is accompanied by pain, the greater is the increase of leucocytes—that is, the increase of the cells keeps pace with the extent of the inflammatory serous surface. Once more, in inflammation of the mucous membrane the same principle is manifested. In acute bronchitis the excess of leucocytes subsides with lowering of the temperature and decrease of expectoration (if purulent); but if the temperature comes down and the expectoration remains of the same quantity the excess of leucocytes is not affected. It appears, too, that the leucocytes increase more when the expectoration is green than when it is of other kinds. The same increase is found in inflammation of other mucous membranes—in diarrhoea, dysentery, acute laryngitis, and cystitis. The results obtained from the examination of the blood of phthisical patients have been very interesting. The leucocytes are sometimes very abundant. I found that whenever high temperature, green expectoration, and auscultatory accompaniments were present together, the increase of leucocytes was well marked. On the other hand, if there were no accompaniments on auscultation and the expectoration was not green, even if the temperature was a little above normal and profuse night sweats were present, the increase of leucocytes was very slight. This clearly proves that the increase of these cells in phthisis is not the result of the cachexia, but is determined by an inflammatory action, or by the activity of pus-secreting surfaces of cavities, this latter action being practically inflammatory as regards the migration of leucocytes. In pneumonia the excess of leucocytes is generally very marked, and is thus of great diagnostic value. Lastly, in acute inflammation of other organs the same excess is noticed—for example, in tonsillitis, orchitis, eczema—and even in the inflammation excited at the seat of fractures of long bones.

(To be concluded.)

## THE UNITY OF SURGICAL PRINCIPLES IN WOUND AND FRACTURE TREATMENT.

By SAMPSON GAMGEE, F.R.S. ED.,

CONSULTING SURGEON TO THE QUEEN'S HOSPITAL, BIRMINGHAM.

(Concluded from p. 841.)

GENERALISATIONS are proverbially difficult in a science and practice like that of surgery. However sound be their foundation, however close the reasonings by which they are arrived at, their success in particular cases depends on the judgment, skill, and care with which they are applied. To the reservations already made I must add something on "dry dressing," which, unqualified, is a very misleading designation of this plan of treatment. It is certainly entitled to be called "dry dressing," inasmuch as water is not used, and even astringent or anti-putrescent lotions very sparingly so; but success demands attention to all the essentials of the physiological treatment of surgical injuries—immobility, position, and pressure, drainage and infrequent dressing, pure and non-putrescent materials; gentle, patient, and

skilled manipulation; intelligent and unceasing watchfulness of constitutional states.

Fresh wounds without loss of substance are particularly suited for the plan of treatment here recommended. They should be put up without water, the edges accurately in contact; always bearing in mind the necessity of providing for drainage outwards of any effused fluid. Under absorbent pads and elastic pressure, with absolute rest and attention to position, the vast majority of fresh wounds heal rapidly, solidly, and painlessly. When the dressing is changed, which it should only be infrequently, no water should be employed; but if there be any discharge and necessity for cleaning, this can best be done with a pledget of dry lint or of absorbent gauze and cotton; all manipulations to be of the lightest. Such dry dressing simulates the natural scabbing process, but is really more perfect. Wounds of many inches in length heal so directly and perfectly under dry dressing and elastic pressure, that in the course of a few days it is often difficult to detect the fine linear scar on the dry and shrivelled skin. If a fresh wound be attended with loss of substance, some boroglycerine should be poured on the part before application; it prevents too close adhesiveness, and possible bleeding, when the dressing is removed, and has the further advantage of preventing decomposition.

The necessary employment of sutures and adhesive plasters, according to requirements, need not be dwelt upon, and I shall only briefly remark that instead of, or in addition to, such bonds of union, I frequently employ styptic colloid, compound tincture of benzoin, or collodion.

In wounds with large loss of substance, if healing be slow, action may profitably be stimulated by a variety of the well-known astringent applications in ointment or lotion, than which I do not know a better than the old red lotion,<sup>1</sup> with a liberal addition of glycerine. Position, rest, and pressure remain cardinal indications, poultices and water prohibited. By this I mean stagnant water in the shape of water dressing, which is nearly as potent as a poultice in promoting suppuration and decomposition. It is otherwise with cold-water irrigation, which is consistent with, nay may be made conducive to, perfect drainage, and by its astringent and sedative action produces effects very similar to those of rest and pressure. Cold irrigation is not easy to apply continuously comfortably, and one of its great advantages, the low temperature, may be secured by ice bags.

I hope I have made it clear that while the absence of water is a prominent feature of the dry dressing method, an essential is the maintenance of immovable apposition under elastic pressure, whereby the dynamics of the circulation are so controlled that the part is only allowed blood enough to nourish it. Irritation, the great cause of stasis and effusion, is reduced to a minimum, and the part is maintained in a state the nearest approaching to inaction and dryness. In direct proportion the material and the possibilities of decomposition are averted.

Contused and inflamed wounds likewise afford conclusive evidence of the soundness and general applicability of the principles and method just related. The dressing which I hold in my hand was removed from one of the *employés* in an iron warehouse. He was moving some pigs of iron, when one, weighing a little over a hundredweight, fell on his right foot. I saw the case very shortly afterwards, and found the foot very much swollen, its bony outline obliterated, the skin bluish and shining, with a star-shaped wound on the centre of the instep. Having satisfied myself that no foreign body was present, I dried the wound and placed over the dorsum of the foot this fold of lint, well soaked with compound tincture of benzoin, over it this large pad of absorbent gauze and cotton, and then a compressive bandage from the roots of the toes to the middle of the leg. I enjoined my patient to keep perfectly quiet, lying during the day with his head at the foot of a sofa and the injured foot over its head. I did not remove the dressing until the eighth day, when the wound was healed, the outline of the limb perfect, and though the skin was mottled, as from a bruise, up to the middle of the leg, it was cool and painless.

You see how the blood had penetrated, though in small quantity, through the dressings, and dried on the outside. The tincture of benzoin had acted as a coagulant and anti-putrescent, and drying into the lint served the purposes of a

<sup>1</sup> A solution of one to two grains of sulphate of zinc in water, with the addition of some compound tincture of lavender.

mould. Its styptic property was assisted by pressure and position, under which the effusion was absorbed; the part shrank, and the wound healed without any further interference. This result, a typical one of the method, was not a simple consequence of a dry application, but due to a variety of causes which combined in controlling the circulation and promoting reparative action in accordance with demonstrably true principles of animal physics.

A punctured and inflamed wound of a much more serious kind, but with equally happy issue, calls for a few words. I was asked to see a licensed victualler who a week previously, while carving a joint, had thrust the point of a long knife into the centre of the palm of the left hand. He proceeded at once to a neighbouring hospital, where the hæmorrhage was arrested and a carbolic dressing applied. Hæmorrhage recurred the third day, and the padded wooden splint, which I have here, was firmly applied with a calico roller to the hand, and the patient sent home with the request to attend in a few days. The arm swelled, pain was intense, and my attendance was requested. The splint you notice is barely long enough to reach from the tips of the fingers to the wrist—a useless contrivance for purposes of rest, a fulcrum for intolerable pressure under the strong calico roller firmly applied to check the bleeding. I found the palm of the swollen hand full of filth, which I lightly cleaned out with dry lint; blood issued rather freely from the wound, into which I lightly brushed iodised colloid with a camel-hair pencil. I put the man to bed, and raising the limb in the vertical position padded it and bandaged it, interlacing the spiral turns every now and then with a piece of moistened millboard. I left the man in bed, with the hand well raised, in perfect comfort. He had had no sleep for nights, but was never disturbed afterwards; with four changes of pads in a fortnight swelling rapidly subsided, and healing was perfect without an untoward symptom. Pressure over a short strong splint like this is just the oppressive constriction which cannot be borne, and is a source of incalculable mischief. On the other hand, the equable elastic pressure subsequently employed, with absolute rest and position on sound principles of vital dynamics, conduced to a surgical result in which the dry dressing was merely one factor.

Only the other day I was asked to see this case in consultation. A gentleman had bruised the front of his leg against the step of his carriage. The part injured was not the shin, as is usual, but the muscles outside it. Cooling lotions had been applied for two or three days; but, swelling and heat increasing, poultices were substituted, and an incision for the evacuation of matter was contemplated when I was called in. I found the part much swollen, red, and tender, and have no doubt that an opening would have given exit to pus. But the patient being very averse to the knife, I consented to endeavour to avert it, while stating clearly that the surgeon was justified in recommending it. With his assistance I raised the limb vertically, padded it and bandaged it over interlacing strips of wet dextrined millboard from the toes to the knee. The patient was ordered to remain in bed with his leg in a swing. In a few hours the bandages and millboard lattice-work were comparatively loose. Every twelve hours an outside bandage was applied with equable pressure, and at the end of forty-eight hours the limb was exposed; we found it pale, cool, shrunken, and painless.

If this may seem to point to a too mechanical doctrine of inflammatory development and treatment, I beg you to recall your experience of the everyday surgery of the upper and lower limbs. How rare are congestions and ulcerations of the former, how common of the latter. Here is a big, boggy, red leg, with a saphena vein nearly as big as an index finger, and an irregular, dirty red, filthy sore, nearly as large as the palm of the hand, the surface of the limb tense and shining, and often so tender as scarcely to bear being touched with a feather. Put the man on his back, raise the leg vertically by the heel, in one minute by accurate test I have found the circumference at mid-calf diminish exactly one inch. While an assistant supports the heel, strap the leg from the ankle to the knee with perfectly equable pressure, leaving two or three narrow interspaces for drainage opposite the ulcer. Over the plasters covering it, and surrounding the leg, place a good large pad of absorbent gauze and cotton; then bandage spirally and evenly from the toes to the knee with a good compress over the vein. If the patient can rest a day or two with his leg in a swing all the better; but even if he walks about at once, the compressive apparatus soon becomes loose. When it is opened in two or three days

the pad is full of discharge, the limb much shrunken and paler; cleanse it with dry lint or absorbent cotton, reapply the same apparatus, change it every fourth or fifth day, and healing progresses in comfort and without a check. Should the sore seem languid at any one of the dressings, it may be beneficially lightly touched with sulphate of copper, or have a zinc and glycerine lotion brushed over it, with a camel-hair pencil. In the main, the state of such a leg is owing originally to disturbed nutrition from interference with the circulation by mechanical causes. So, too, its healing is brought about by restoring that balance of physical conditions, which is essential to the equilibrium of blood-supply, innervation, and healthy nutrition.

On the same principles, and practically by the same method, most cases of so-called erysipelas after injury may be successfully treated. Under wet applications they spread; whereas they rapidly subside under the elastic pressure of dry absorbent gauze and cotton pads and perfect bandaging. Even when the subjacent tissues have become sloughy, and matter has formed, subsidence on the plan indicated is most rapid, all the more so if due attention be paid to position, and digital compression be applied to the main artery. These principles of treatment follow physiological lines. Injuries are serious in direct proportion as they interfere with the exercise of healthy living functions; to preserve and restore them must be the surgeon's great aim in treatment; and he will be successful in direct proportion as he imitates and assists the natural processes.

To those who have noticed the omission of reference to so-called antiseptic surgery, I beg permission to address a few remarks. Life is the great antiseptic. Preserve it, restore healthy function, control by rest, position, and pressure, nervous, vascular, and muscular action, so as to minimise the material for, and the causes of, discharge, carry it off as it is produced by drainage-tubes and absorbent dressings, and the repair of injuries proceeds like healthy nutrition, uninterruptedly and painlessly. That infection is always floating in the atmosphere, ready to settle in the shape of impalpable and implacable germs into any breach which may be made in the surface of a living body, is an idea which has never troubled me.

When, in 1867, Sir James Simpson was working out his acupuncture, he applied to me for some information, suggested to him on reading my papers on "The Present State of Surgery in Paris," just previously published in THE LANCET. To illustrate one point, I requested my then house-surgeon to tabulate all the operations of any moment which I had performed during his tenure of office, a period of about two years and nine months, during which I had discarded poultices, water dressings as little better, and dressed wounds mainly by rest, position, and pressure with pads of dry lint. Excluding a large number of minor operations, all of which were successful, the total reached 107 operations, amongst which were three of lithotomy, ovariotomy two, fistula in ano twelve, trephining skull one, removal of bony sequestra six, ligature and division of varicose veins two, removals of female breasts twelve, removals of tumours sixteen, excision of elbow four, amputations of arm, wrist, thigh, leg, and ankle twelve, partial amputations of hand and foot twenty-five, with the result of three deaths in 107 operations, an average of my general surgical experience. The prescription to rub strong carbolic acid into the innermost recesses of a compound fracture, to pursue and kill the germs; the warning that an antiseptic dressing may lose all its potency through a hole no bigger than a pin's point in the investing mackintosh, admitting countless germs; that a dressing must be changed so soon as a little discharge permeates it, lest a septic channel be established for the ubiquitous and maleficent vibrios; that these will settle down as a swarm from the air on a granulating sore if the spray be not kept in action while it is dressed,—are a few of the fallacies which have never had any dread for me. That as accessories to wound treatment antiseptics possess real value is an old truth, for insisting on which the world will ever be indebted to those from whom I have felt compelled to express qualified, but material, dissent. Their error has consisted in exaggerating incidents and underrating essentials; in predicated from experiments on dead organic matter the action of living tissues; in pretending to found a new surgery; in under-estimating truths which may not have the allurements of novelty or of speculative generalisation, but which are none the less the demonstrably sound foundations of surgery as a science, one and indivisible.

If, dealing with facts and principles, I have not mentioned authors by name, it has been for two reasons. I have been anxious to steer clear of personal controversy, which is one of the most formidable obstacles in the way of calm discussion; and it would have been impossible to refer to some authorities without seeming, but unintended, disregard of others.

Far from underrating the importance of the literature and history of the subject, I feel very deeply that if it had been better known, there would be less necessity for combating errors long since exposed, and insisting on truths inadequately appreciated or undeservedly forgotten.

Addressing myself, as by your permission I have had the privilege of doing this evening, to the Medical Society of London, I have felt that this was no occasion for a display of surgical erudition; I have rather fixed upon it as a good opportunity to elicit, by plain statement, an expression of opinion to test the possibility of agreement, after elimination of unsubstantial differences, on the essential unity of surgical principles in the treatment of wounds and fractures.<sup>2</sup>

## CASES FROM COUNTRY PRACTICE<sup>1</sup>

By H. MALLINS, M.B., M.Ch. T.C.D.

### CASE OF TUMOUR OF THE CEREBELLUM.

ANNE L—, aged sixty-one years, a labourer's wife, the mother of a numerous family, first came under observation on March 15th, 1881. Her family history is very good; her mother is still alive. With the exception of some gouty attacks, she has enjoyed good health until about a year ago, when she commenced to complain of headache. She was considered to be suffering from migraine, and improved somewhat under treatment directed against that affection. The pain in the head, however, did not entirely leave her, and towards the end of July it again became very severe, radiating from the occipital region forwards all over the head, attended with frequent vomiting and extreme tenderness of the scalp. Double vision was now noticed for the first time. No paralysis could be made out, but a condition of general muscular debility was well marked. From this time to the date of her death she was confined to her bed. When able to walk no tottering gait had been noticed. The diagnosis of a tumour of the cerebellum was now made, grounded chiefly on the two symptoms of persistent pain in the head and constant vomiting.

Nov. 1st: The pain is now referred more to the right frontal region than elsewhere. Since last report the sight of the left eye has been completely lost; both pupils are normal. There has been no vomiting for the last two weeks. —7th: The sickness has returned. There is slight left strabismus. The sight of the right eye is becoming affected. The conjunctivæ of both eyes are injected, and are the seat of much "pricking and watering." —14th: The pain, which is as severe as ever, is now described as being of a pulsatile character, and is felt all over the head. The sight of the right eye is a little improved. A feeling of numbness is felt over the whole body when she assumes the standing position, which she cannot do without assistance. The vomiting continues, though occasionally ceasing for a few days. The tongue is coated with a thick whitish fur, and has been so for several months past. She complains very bitterly of the unpleasant taste in her mouth. The bowels are obstinately constipated, and only respond to a sharp purgative. —19th: The sight of the right eye is nearly gone. Her hearing seems affected now. When spoken to she turns her head away from the speaker as if the voice seemed to come from a point opposite the real one. The intellect seems to be getting clouded. The general muscular paresis is more pronounced. —22nd: Both pupils dilated, and insensible to light. Convergent strabismus of eyes, more decided on left side; the oscillation of both eyeballs prevented a satisfactory

examination with the ophthalmoscope. She can still see, but very imperfectly, with the right eye; still complains of a nasty stinking taste in her mouth. Pulse 72, intermittent. Respiration very slow, 12 in the minute. A numb feeling of "pins and needles" in both hands and feet, accompanied by a sensation of cold in the parts, is now complained of.

Jan. 31st, 1882: Pain of head continues. It now extends down the back of the neck, accompanied by stiffness of the latter. The sight of both eyes is now gone.

Feb. 16th: The vomiting has ceased since last report. Beyond a tendency to delirium at night, there is no change to record.

March 5th: Intellect more clouded; keeps talking to herself, though sensible enough when roused. The pain in the head now comes on in paroxysms, attended with slight muscular contractions of the limbs. —31st: Slowly getting worse; passes everything under her; vomiting very rarely occurs now; she has great difficulty in moving either upper or lower extremity as she lies in bed. Bedsores are beginning to form over the sacrum.

April 12th: Complete paralysis of both upper and lower extremities; has great difficulty in swallowing; is almost unconscious, answering yes to every question. —20th: Sank quietly at 1 P.M.

Autopsy, twenty-eight hours after death.—Head alone examined. Dura mater slightly adherent to calvaria in the left fronto-parietal region. Upper surface of brain healthy in every respect. On viewing the base of the brain, however, the eye is at once struck by a tumour of a dark reddish-blue colour (very like a piece of placenta), lodged between the pons Varolii, whose substance it has deeply indented internally, the left lobe of the cerebellum posteriorly, and the cerebral mass anteriorly and externally. Irregularly roundish in shape, about two inches in diameter, of soft, friable consistence, it seems to spring from the upper surface of the left lobe of the cerebellum, with the pia mater of which it has a very intimate connexion. The tumour was examined by a special committee of the Norwich Medical and Chirurgical Society, and pronounced to be a glioma.

Watton, Norfolk.

## NOTES ON MEASLES.

By WALLACE B. CROSKERY, L.K.Q.C.P.I., &c.

I HAVE before me notes of many cases of measles which came under my own observation, and having taken those notes with the special object to, at one time, define clearly for myself, and possibly for others, special points in the disease, I think that I might now draw attention to the points I arranged my notes to make clear. The first points in the disease to which I wish to call attention are the slight amount of exposure to contagion necessary to contract it, and the early period at which infection may be given off.

W. C—, the son of a medical man, was sitting at home when his father entered the room, having come straight from a case of measles. The latter, forgetting that he had omitted to take the usual precaution to disinfect his hands, bent over the son and stroked his face several times. Suddenly he remembered the case he had just left and his sin of omission, and at once passed over the boy's face a towel sprinkled with a solution of carbolic acid. W. C— sickened in ten days with measles. This case will illustrate the slight amount of exposure necessary, and the communication of the disease through a third person. C. D— drove in the same cab with W. C— to school; on the same day W. C— came home early, shivering, and with a temperature of 101°. On the morning of the fifth day, or ninety-six hours after invasion, the rash of measles developed on W. C—. In the course of ten days C. D— sickened. This will illustrate exposure on the very first day of invasion, followed by the communication of the disease. I have had many cases which came under my observation before the eruption where, suspecting measles coming on, I had complete isolation with the usual disinfecting precautions observed, and yet the disease developed in due course among other members of the family.

Period of Incubation.—I have seen various statements as to this, some writers on the subject giving a much longer time than I have yet observed. In the great majority of cases nine to ten days after the exposure the premonitory symptoms set in. I have some where eleven days, and a

<sup>2</sup> For a report of the discussion on this paper at the Medical Society of London, see THE LANCET, Nov. 18th, p. 851. All the dressings and materials referred to are prepared by Messrs. Southall Brothers and Barclay. A handy and elegant case, containing absorbent and antiseptic pads and bandages, plaster splints, styptic colloid, boroglycerine, ether, and instruments for the treatment of surgical injuries on physiological principles, has been arranged by Messrs. Salt and Son, Surgical Instrument Makers, Bull-street, Birmingham.

<sup>1</sup> Read before the Norwich Medical and Chirurgical Society.

few where twelve days, elapsed before the disease showed itself. I am disposed to think that the long period is where the patients have more resisting powers, as my cases of twelve days, whether accidental or otherwise, were the parents who took it from their children. I think the one exposed to contagion, after a quarantine of fourteen days, may, in the vast majority of cases, be declared to escape the disease, if he or she has a normal temperature and none of the symptoms after the lapse of that interval.

*Period from Invasion to Eruption.*—This period I consider full of interest, the special points being the temperature and the day of eruption. The disease occasionally sets in with a temperature of  $101^{\circ}$  or higher. Frequently on the second day, especially in the morning, the temperature has gone down to normal; so that at this stage, when sometimes the other symptoms are badly marked, the ailment may be declared—unless one has considerable experience in the course of measles—to be simply a feverish attack now passing off. On the third day, however, the temperature again rises, and the symptoms become more obvious. The highest temperature is usually reached about twelve hours before the eruption, at the eruption, or twelve hours after the eruption begins to come out. A temperature of  $103.5^{\circ}$  I should set down as the average at this period, though I have frequently seen  $104^{\circ}$ , and occasionally  $105^{\circ}$ . I have watched several cases from day to day, and have notes of two cases where no eruption whatever appeared till the morning of the fifth day, or ninety-six hours after the first rise of temperature was observed. Occasionally, however, I have seen it make its appearance at the close of the third day, but much more frequently on the morning or evening of the fourth day—that is, from seventy-two to eighty-four hours after invasion. I have dwelt on these two points more especially as one does not often see cases of measles till the eruption has already appeared, and my object has been to show that, notwithstanding the temperature occasionally falling to normal twenty-four hours after invasion, or notwithstanding four entire days elapsing without rash, still measles is in no way contra-indicated.

*Eruption to decline.*—The temperature generally falls rapidly once the eruption has well appeared. In from twelve to twenty-four hours after the highest temperature has been reached I have seen a fall of from three to four degrees frequently, with possibly a subsequent rise of a degree or two twelve hours after. Normal temperature in an uncomplicated case is reached on the seventh or eighth day after invasion. The respiration should always be counted as the time for eruption approaches, and for a day or two after it has already approached, and the chest occasionally examined. The respiration about this period may number thirty, thirty-five, or even forty, without any bronchitis or pneumonia being present; but any greater number, unless the temperature is very high, will usually indicate some chest complication. I say unless the temperature is very high, because I have seen from fifty to sixty respirations per minute due to a temperature of  $105^{\circ}$ , where no abnormal condition of the lungs or bronchial tubes existed.

*Isolation.*—This, with the usual disinfecting precautions, ought to be commenced as early as possible, and carried on for some time after the eruption has disappeared. I generally advise at least a week to elapse after the fall of the temperature to normal, or the entire disappearance of the rash, before I allow my patient to see anyone other than those engaged in nursing. During this interval the patient has a couple or three baths, using carbolic soap freely. I think, then, after the room and clothes have been disinfected, all contagion is gone.

There is one misleading symptom occasionally present in the early stages to which I wish to direct attention. I refer to the character of the cough. I have seen it of such an exceedingly croupy nature that croup and not measles might be looked for. I had one case, indeed, followed by croupous or plastic bronchitis, where—the measles having subsided—casts of the bronchial tubes were expectorated; but, as a rule, the cough, in the cases where it is croupy, loses this distinctive character after the eruption has come well out.

Downpatrick.

Two "physicians," alleged quacks, have (says the *Medical News*) been fined in New York City for illegally practising medicine. In Great Britain quacks are prosecuted, not for practising, but for using any title or description implying that they are legally qualified to practise.

## REMOVAL OF MALIGNANT TUMOUR OF THE NECK,

INVOLVING THE STERNO-MASTOID MUSCLE AND INTERNAL JUGULAR VEIN.

By G. H. HUME, M.D.,

SURGEON TO THE NEWCASTLE-ON-TYNE INFIRMARY.

SOME years ago attention was drawn to the subject of removal of tumours of the neck by the late Professor Spence, who published two successful cases in which the mass removed was of great size. Mr. Spence pointed out the necessity of carefully determining the nature of the tumour before undertaking such operations, and laid stress upon the signs which distinguish growths of a non-malignant from those of a malignant character. At the time Mr. Spence published his cases he had been able to discover the record of only four similar operations by British surgeons. His cases served to demonstrate the practicability of the removal of even very large tumours underneath the sterno-mastoid when these are of a non-malignant nature, and therefore more or less completely encapsuled, and such operations have frequently been successfully undertaken since. In the case of malignant growths in this situation, on the other hand, it is usually laid down that they ought not to be interfered with. But to this rule there are exceptions, and an attempt at removal seems to be justified whenever recent origin, fairly defined limits, and comparative mobility, render it probable that the growth can be entirely extirpated.

The following case is recorded as an instance of such a tumour which though involving important parts admitted of complete and, so far as can be judged, successful removal.

Mr. B—, steamboat owner, aged sixty-six, was sent to consult me in March last by Dr. Peart of North Shields, on account of a tumour of the left side of the neck. It had been noticed four months, and was increasing rather rapidly. It had been occasionally the seat of pain, and beyond a slight interference with swallowing did not cause other inconvenience. There was no engorgement of the veins of the face. The growth, which was hard and nodular, extended from the level of the upper border of the thyroid cartilage to the clavicle, being situated underneath and evidently involving the sterno-mastoid muscle. The limits of the tumour were defined as regards its upper, lower, anterior, and posterior margins, and the overlying skin was free, but an incomplete mobility suggested doubt as to its deep connexions. The tumour was evidently malignant, and its removal without delay was advised. The operation was performed on March 23rd with the assistance of Drs. Peart and E. Brumwell. An incision was made through the skin from below the mastoid process to the clavicle, and a second incision was made backwards from the first so as to obtain space. The clavicular part of the sterno-mastoid was next cut through above and below the tumour, and as the sternal portion was not involved it was separated and displaced to the front. The mass was then freed behind and inferiorly. The omo-hyoid was found to enter the tumour and was divided. In clearing the inferior border the dissection was pursued carefully till the deep vessels were reached. It was then found that the growth was closely connected to the internal jugular vein, and a double catgut ligature was passed round the vessel and held in readiness. Continuing the dissection upwards, the tumour was seen to be closely attached to the anterior wall of the vein for the extent of about three inches. The ligature which had been passed was therefore tied, and the vein divided. A second double ligature was in the same way applied, and the vein divided above its connexion with the tumour. There was then no difficulty in separating the mass with the adherent portion of vein from the carotid artery and pneumogastric nerve, and completing its removal. The descendens noni was not seen. The patient went on well after the operation. For a few days he had difficulty and pain in swallowing, which seemed mainly due to the disturbance of parts which the act involved. The lines of incision healed almost by first intention, but discharge continued from the cavity for some time, and the drainage-tube was not finally removed till the end of three weeks.

Microscopic examination of the growth showed it to be

carcinomatous. It consisted of cells of irregular form, with multiple nuclei, the cell-masses being traversed by connective-tissue stroma. There has been so far no return of the disease. Newcastle-on-Tyne.

## DEATH AFTER ABDOMINAL OPERATIONS FROM HEART-CLOT, DUE TO DISEASE OF THE KIDNEYS.

By LAWSON TAIT, F.R.C.S. ENG.

DEATHS after any kind of abdominal operation are now becoming so rare, from the elimination of preventable causes, that we seem likely to gain an insight into causes which are not preventable. Amongst these, in my recent experience, the most prominent has been heart-clot. In deaths after ovariectomy it seems to be clearly associated with the impoverishment of the blood resulting from repeated tapings. But it has occurred to me twice lately in other cases, where tapping was not an element. One was a case of removal of the uterine appendages for chronically inflamed and adherent ovaries, and the other was a case of removal of a pediculated myoma. The patients were respectively forty-one and fifty-one years of age, and in neither of them did examination of the urine give any evidence of disease of the kidneys. They both died in the same way thirty-six hours after the operation, the only feature being an extremely rapid rise of the pulse beginning in about twenty hours. The conditions found after death were precisely the same: adherent clot in the heart chambers and (to quote the words of Dr. Saundby, who made the post-mortem examinations) "both kidneys small, the capsules adherent, the cortices narrow, not more than one-eighth of an inch in breadth." The details of the operations were found to be quite satisfactory.

The facts of these two cases are too closely identical to form a mere coincidence, and from my past experience I feel strongly that, but for the condition of the kidneys, they would both have recovered.

I write this note to ask help from those who are familiar with kidney troubles upon two points: Could I have discovered, in any way at present unknown to me, the state of the kidneys, and could I have done anything in the way of preparatory treatment to prevent the formation of the heart-clot? I have removed tumours, in many instances, knowing of the existence of serious visceral disease, including Bright's disease, and the patients have recovered. But in this (to me) unrecognisable kidney atrophy there seems to be a serious bar to operative success.

Birmingham.

## A Mirror OF

## HOSPITAL PRACTICE, BRITISH AND FOREIGN.

*Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.*—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

### ST. THOMAS'S HOSPITAL.

#### MALIGNANT DISEASE OF THE PYLORUS; REMOVAL; DEATH.

(Under the care of Dr. BRISTOWE and Mr. SYDNEY JONES.)

THE following are the details of the case of excision of the pylorus mentioned in our columns on the 28th ult., p. 720.

J. B—, aged fifty-seven, a stationer's assistant, was admitted into the hospital under the care of Dr. Bristowe on Sept. 22nd, 1882, with the following history:—He had always been healthy, never having had any serious illness, until the beginning of last May, when he complained of tightness over the upper part of the abdomen, with loss of appetite and inability to take fatty food without a feeling of nausea and regurgitation. From that time the feeling of tightness, with increasing soreness of the region mentioned,

had continued, and he had had occasional vomiting. He had also lost sixteen pounds in weight during the time. When admitted under Dr. Bristowe's care his condition was as follows:—Patient much emaciated, and complaining of pain in the abdomen on movement, followed by a feeling of sickness and of loss of appetite. On examination of the abdomen a hard, rounded, but somewhat irregular lump, from one and a half to two inches in diameter, is to be felt a little below the ribs on the right side, it is readily movable within narrow limits, and chiefly in the vertical direction; its centre is about an inch above and two inches to the right of the umbilicus. Its dullness is apparently continuous above with that of the liver, its lower edge extends from half an inch to an inch below the umbilicus. Its left border is about a finger's breadth, and its right border about four fingers' breadth, from the same part. It pulsates, but the pulsation is evidently communicated from the aorta. Liver dullness begins at the sixth rib, and is continuous with that of the growth; edge cannot be felt. Spleen normal. Tongue is a little coated. Appetite variable; no vomiting. Bowels open. Nothing abnormal in chest. Urine 1020; no albumen, lithates.—Sept. 6th: Was sick this morning for the first time since admission. Bowels regular. Sleeps fairly well at night.—27th: No further vomiting; felt a good deal of pain in the night, which he describes as a burning heat in the stomach.—29th: Patient feels easier this morning, has had no return of the sickness. Abdomen is not nearly so tender as it was.

Oct. 3rd.—Tongue coated, white, and dry; appetite good, bowels open. Complaints of shooting pains across the umbilical region, and distension after eating.—6th: The patient is expectorating a good deal, but there are no abnormal signs to be detected in the lungs. Resonance extends round the tumour, excepting perhaps for a short distance where it adjoins the liver. From this date until the 15th there was no marked change beyond the gradual emaciation of the patient and perhaps slight increase in size of tumour; he only vomited very occasionally, complaining chiefly of distension after food and slight pain in the tumour, which was apparently lower down and more fixed, not moving with respiration. There had been no elevation of temperature whilst he was under observation.

The question as to the nature of the tumour was carefully considered and discussed from the time of the patient's admission up to the time of the operation. The possibility of its being an enlarged and diseased gall-bladder, a movable kidney, an aneurism, or a growth originating apart from the stomach in the peritoneum, had due weight given to it, and was fully argued out. The only one of the alternatives that seemed to deserve any serious consideration was that of its being a tumour originating in the great omentum or some other part of the peritoneum, and this would scarcely have deserved entertaining were it not for the fact that some of the most common and distinctive signs of pyloric disease were absent in this case. The patient while in the hospital enjoyed a fair appetite, he was very rarely sick, he never vomited blood, and the stomach was not greatly distended. Further, it was thought by some that the situation of the tumour was lower than could be well explained by its being a tumour of the pylorus. Dr. Bristowe, however, whilst admitting the possibility of its being a peritoneal growth, adhered to the opinion he had at first formed, that the case was one of carcinoma of the pylorus. The patient from the first expressed a strong wish to have the growth, whatever it was, removed. And considering that, notwithstanding his fair appetite, he was steadily growing weaker and thinner, at length it was determined to consult Mr. Sydney Jones with respect to the feasibility of an operation, and to put the matter plainly before the patient. The operation was not urged upon the patient, and the risk attending it was put before him clearly. He decided to have it performed. No doubt the patient would have lived some little time longer had his case been left to nature. But it was felt that any hope of benefit would be much greater now than if the operation were put off until the patient was sinking. In a former case, too, which had been under Dr. Bristowe's care, and the question of removal of diseased pylorus had been considered and determined upon, the patient only gave his consent when he was moribund, and too ill to have any operation performed.

Mr. Sydney Jones having agreed to operate, on the 15th of October the stomach was washed out with water, and from that date until the 17th he was only allowed skimmed milk, taking about two pints daily. The stomach was again

washed out about an hour before the operation, which commenced at 2.15 P.M. of the 17th, and was carried out under the spray (1 of carbolic acid to 80 of warm water), and afterwards dressed with antiseptic precautions in the usual manner. Ether having been administered, Mr. Sydney Jones made an oblique incision extending from left to right, commencing an inch to the left of the middle line and four inches below the ensiform cartilage, four and a half inches in length, inclined downwards, carefully dividing the various layers until the peritoneum was reached, when, having arrested all hæmorrhage, the peritoneum was divided on a director to the extent of the previous incision. In the upper part of the wound, which gaped widely, the border of the liver was seen rising and falling under the costal arch with respiration, which was then jerky and irregular, whilst the growth was exposed about the centre of the wound. The gall-bladder was not seen. Slightly to the right of the middle line was a vertical band passing upwards to the liver and covered with a reflexion of the peritoneum, this, which was the round ligament, was divided between a pair of clamp forceps and both ends of a small vessel ligatured. Other peritoneal adhesions existed in this neighbourhood. The tumour, which was larger than a duck's egg, was connected by numerous adhesions to the surrounding parts, and below it, close to the head of the pancreas, were a good many infiltrated glands about the size of small nuts. The great omentum was divided in pieces between double ligatures. The tumour being now more free, the stomach was lifted up towards its pyloric end and flannels wrung out of warm water were placed under it to prevent bleeding into the peritoneal cavity. The lesser omentum connected with the pyloric end of the stomach was gradually cleared from the tumour by cutting between pairs of artery clamps and ligaturing both ends of the section. There was a good deal of hæmorrhage close by the head of the pancreas, for the most part venous. When the pyloric region was thus made more free, an opening was carefully made over the finger introduced from below in the lesser omentum to the left of the growth. The pyloric artery was then ligatured and divided. Then a Rydygier's clamp was put round the stomach by introducing one limb through the opening in the lesser omentum, and passing the other across the anterior surface; it was then closed, and the stomach divided to the right of it. The clamp was then removed, and hæmorrhage from the cut surface arrested; this was not considerable, only a few minute points requiring ligature; the stomach was found to be empty, and the mucous membrane appeared to be quite healthy. The cardiac end of the stomach was carefully sponged out. A little brownish fluid was seen at the pyloric orifice; a small sponge was placed in each orifice. The clamp was next placed on the duodenum just beyond the tumour, and the growth with some infiltrated and adherent glands removed. The duodenum was firmly held up when divided to prevent retraction. The growth was seen to extend a little further down the duodenum on its posterior border, so a small piece, including this, was removed by scissors. There was very little hæmorrhage on removal of the clamp, and a few fine ligatures proved sufficient. The upper part of the duodenum was mopped out, and a clean piece of sponge introduced. As the section of the stomach was larger than that of the duodenum, the upper part of the former was stitched together, for about two inches, by means of nine sutures of fine carbolised silk, through its mucous membrane, and a corresponding number of the same material, including muscular and peritoneal coats. The cut ends of the stomach and duodenum were now brought into apposition, and corresponded well in size. The posterior part of each was then sewn together with fine carbolised silk, the mucous membrane being carefully adjusted last, the first sutures applied being passed between the mucous and muscular coats, perforating the latter and the peritoneum, and then passing through the peritoneal and muscular coats of the apposed edge; as the opening became smaller it was not found possible to pursue the same plan towards the front, and here Lambert's stitches only were used. There were about fifty-two silk sutures put into the stomach and duodenum. The parts around were carefully cleansed, the flannels having been removed, and the stomach placed in position again. The external wound was closed by means of seven or eight deep silk, and four superficial catgut, sutures. During the course of the operation, which lasted almost three hours and a half, the patient became much collapsed, and it was found necessary to bandage his limbs and administer a brandy enema.

After he was put to bed, in addition to the above means, hot blankets and hot-water bottles were applied, and another brandy enema given. He became conscious about 8.30 P.M., complained of pain and asked for morphia, but gradually sank, dying at 11.15 P.M.

A post-mortem examination was made on the following day by Dr. Sharkey. The body was much emaciated. Rigor mortis well marked in both extremities. Pleuræ adherent by old adhesions, at left apex and right base. Lungs a little collapsed, otherwise normal. Pericardium and heart natural. Liver small and pale, at the upper border of its right lobe was a nodule of new growth about as large as a walnut. Kidneys normal. On opening the abdominal cavity, by enlarging the incision of operation, the peritoneum looked almost normal. All that was remarkable were some dotted hæmorrhages about the pyloric end of the stomach, and an exceedingly small quantity of red fluid on the surface of the coils in the neighbourhood. One could scarcely see without close examination that any operation had been done, as the stomach, colon, &c., occupied their normal positions, and the stomach had its normal shape.

The carcinomatous growth removed measured one inch and a quarter along its upper border, and three inches and a half along the lower, its base was of a firm fibrous character, completely surrounding the pylorus and adjacent portions of the stomach and duodenum, and the inner aspect presented a fungating ulcerative surface, the lumen of digestive tract at this point only just permitting the passage of a small finger.

#### PUBLIC HOSPITAL AND DISPENSARY, SHEFFIELD.

SEVERE WOUND OF THE ANKLE-JOINT; RECOVERY WITH  
MOVABLE JOINT.

(Under the care of Dr. KEELING.)

FOR the following notes we are indebted to Mr. G. F. Gubbin, house-surgeon:—

W. H—, a boy, eight years of age, was admitted on Aug. 8th, 1882, with an extensive wound of his left ankle-joint posteriorly, caused by the cutting portion of a mowing machine. On examination it was found that the wound extended across the back of the joint, from below the internal to the external malleolus, the lower portion of which was separated from the rest of the bone and broken into fragments; the tendo Achillis was completely divided, as well as the peroneus longus and peroneus brevis muscles on the outer side. The joint was laid open and the cartilaginous surfaces of the bones entering into its formation exposed; some of the cartilage had been chipped off. There had not been much bleeding. Under the carbolic spray the wound was freed from fragments of bone and cartilage, and carefully cleaned; the two ends of the tendo Achillis were brought into as close apposition as possible and fixed with carbolised catgut sutures. The wound was then sewn up with silver wire and catgut sutures and enveloped in the ordinary antiseptic gauze dressing, the limb laid on its outer surface, and the ankle-joint fixed in the extended position. The wound was dressed twice during the first eight days, afterwards once a week until Aug. 30th (or twenty-two days after the receipt of the injury), when it was found to be quite healed. The boy was kept in bed and passive movement practised.

On Sept. 11th he was able to flex and extend the joint freely, and to invert the foot, but the power of eversion was rather weak; he was not able to bear much weight on the limb. He was now allowed to get up. The boy continued to improve, and on September 20th it was noted that he could get about with ease, although not able to bear the whole weight of his body upon the injured limb. When he was lying on the bed it was found that he could move the wounded joint just as freely as the sound one.

#### BRITISH MEDICAL TEMPERANCE ASSOCIATION.—

The next quarterly meeting of the Association will be held in the Medical Society's Rooms, Chandos-street, Cavendish-square, W., at 4 P.M. on Nov. 22nd, 1882. Dr. Richardson, F.R.S., will preside. A paper will be read on "Inebriety caused by Mental Injuries," to be followed by a discussion, in which all medical men will be at liberty to take part.

THE collections made at Chapel-Allerton Church on Sunday, the 12th inst., for the Leeds medical charities, amounted to £78 11s. 6d.

## Medical Societies.

### PATHOLOGICAL SOCIETY OF LONDON.

THE ordinary meeting of this Society was held on Tuesday, November 21st, Dr. George Buchanan in the chair. He presented the new volume of the Transactions to the Society, and also announced that in April next there would be a discussion on the pathological condition of the various organs in diabetes.

Dr. HORROCKS showed a living case of Bromide of Potassium Rash in a girl aged ten years, who had been taking twenty-five grain doses of bromide of potassium twice daily for four months; one month ago red swellings like erythema nodosum appeared over the tibiae, and a week later pustular points were present on the swellings, and coalesced; shortly afterwards it came upon the extensor aspect of the arms and forearms; there was no rash elsewhere. The rash was now undergoing involution and was not so characteristic as it had been. Dr. Horrocks alluded to the absence of the rash in the usual acne situations and thought it was rare to find it on the extensor aspects of the limbs only.—Dr. THIN considered that these cases presented sufficiently characteristic features for them to be diagnosed independently of the history and alluded to a case in which he had done so. His microscopical investigations in a case of iodine rash led him to consider that the condition was not due to inflammation of the sebaceous glands and therefore not a true acne, but that it was due to the drug affecting directly the walls of the vessels, producing stasis and its consequences.—Dr. RADCLIFFE CROCKER said that the presence of the rash upon the extensor surfaces was not so rare as Dr. Horrocks seemed to think; several cases had been shown by Dr. Barlow, himself, and others, with the rash in these positions, and he described a case now under his care at the East London Children's Hospital of a girl aged nine, who after taking ten-grain doses of bromide for a week showed the characteristic pustules upon the anterior surfaces of the legs and on the arms and chest; the drug was not stopped, on account of the fits from which she suffered, but some arsenic was given; the following week superficial abscesses two inches in diameter were present on the site of many of the pustules. The patient had been half starved.

Dr. HOGGAN showed and described microscopical specimens of Multiple Lymphatic Nævi of the Skin. He considered that the condition was a common one, though hitherto unrecognized, and that it was probably the early stage, or predisposing cause of many other diseases connected with the lymphatic system, such as, elephantiasis, lymphangions, &c. It differed from the case of lymphangiectodes presented to the Society by Drs. Tilbury and Calcott Fox, as that had no navoid development of lymphatics, and also from Hebra's case of lymphangioma tuberosum multiplex, which, both from the drawings and description, he thought was not a lymphatic disease at all. His patient was a boy, aged nine years; the nævi were of the size of a split pea, flattened, and of a transparent pale-lilac tint, and were situated upon the right leg and ankle, which had been repeatedly attacked by an erysipelatous inflammation, causing great pain and slight thickening of the ankle; in short, the symptoms of the early stage of elephantiasis Arabum. The epidermis was infiltrated with the branched cells of Langerhaus. The abnormal lymphatics traversed the whole thickness of the dermis below, but above did not extend higher than the normal lymphatics, nor nearer than usual to the hair-follicles or sweat glands. There was nothing abnormal in the structure of the lymphatics individually, and the fact that none of the nitrate of silver injection had been extravasated showed that they were actually walled tubes. He thought the disease was an early and curable stage of elephantiasis cruris.—Dr. PYE SMITH asked if the affection was congenital.—Dr. THIN endorsed Dr. Hoggan's opinions as to the structure of the tumours, but doubted their relationship to elephantiasis Arabum, as there was none of the imperfect fibrous tissue seen in that disease. He thought the case corresponded with one described and figured by a Russian observer in the *Archiv für Dermatologie* a few years ago.—Dr. HOGGAN replied that it was in a stage before the development of fibrous tissue; and with regard to its being congenital, thought that it was, but the history was defective on that point.

Dr. SAMUEL WEST showed and described a specimen of Sarcoma of the Bladder and Prostate. The patient was a man aged twenty-one, and showed no symptoms of disease until a month before death, when he had retention of urine; no trace of a tumour could be felt by the rectum. A few days later hæmaturia, followed by retention occurred, and the catheter had to be used; the hæmorrhage continued to be profuse, and he died of exhaustion. Post mortem in the position of the prostate was a tumour nearly as large as the bladder, and in the bladder were several polypoid tumours, the largest rather larger than a Tangerine orange; one was in the trigone, and another projected into and blocked up the dilated urethra; signs of hæmorrhage were present in it, and doubtless it was the source of the bleeding and cause of the retention. The tumours were split up but not villous; section of the prostate tumour showed it to be a soft, round, and spindle-celled sarcoma. There were no secondary growths, the kidneys were studded with small abscesses, and the ureters and pelves dilated, the bladder being hypertrophied, which was good evidence that though there were no symptoms until a month before his death, the tumours were present for a longer period. The delay in the development of symptoms reminded him of the case of mediastinal tumour that he had showed, in which there were no symptoms until two months before death.—Mr. ROGER WILLIAMS said that growths like this were much more common in elderly people. The practical point was, Were these growths infective? Evidently these were not, and he compared them to those medullary growths of the bladder and rectum which were often non-infective. He then showed his museum specimen, which had no history attached to it, of a small tongue-like growth at the neck of the bladder, which had belonged to a boy; the bladder was hypertrophied.—Mr. BARKER mentioned several cases of tumours of the bladder, in all of which he had noticed this feature in common—namely, that the growths were more or less polypoid, whether they were cancers or sarcomas.

Dr. HENDERSON showed a Heart with Syphilitic Gummata in the Wall of the Left Ventricle, and microscopical specimens in illustration of it. A man, aged thirty, was brought in a moribund condition to St. Mary's Hospital, and died in a few minutes. It was stated that he had seemed well until a fortnight before his death, when he began to complain of faintness and pain in the precordial region. On his way to his work he suddenly staggered and fell, groaned, put his hand to his heart, and was unconscious from that moment to his death. At the post-mortem examination the only organ affected was the spleen, which weighed twelve ounces; it was congested, firm, and adhered to the parietes. The liver weighed sixty-two ounces, and had a depressed fibroid scar in the right lobe, but was otherwise normal. The heart weighed thirteen and a half ounces. The pericardium over the left ventricle was studded with pale yellowish-white, slightly projecting elevations, and one or two were over the right ventricle. The endocardium of the anterior wall of the left ventricle was studded with similar nodules. On cutting into the septum a mass of fibroid tissue, a quarter of an inch thick and one and a half inches long, and two inches broad, was seen extending into the muscular substance, with which it gradually blended. Microscopically the muscular substance was permeated by tissue, with gummatous characters, but there was no sign of caseous spots, or of fatty degeneration in the muscle fibres. The lumen of the smaller vessels was narrowed by thickening of the intima. He thought that the appearances of this case made it a connecting link between the cases of fibroid degeneration of the heart described by Dr. Hilton Fagge in vol. xxv. of the Transactions, and those of Dr. Burney Yeo in vol. xxvi. There was no history of anginal attacks, and the larger coronary vessels were not blocked in any way; the question arose whether the blocking of the lumen of many small vessels would have a similar effect to the occlusion of the larger vessels, and so cause sudden cessation of the heart's action.

Mr. ROGER WILLIAMS then showed a wax model of a case of Testis in Perineo and Congenital Hernia. Before admission into the hospital there were great pain and tenderness over the tumour on the right side of the scrotum; an ounce of straw-coloured fluid was drawn off by the aspirator, and on taxis the hernia was reduced. The testicle was swollen and tender, and could be felt in the perineum. This position of the testicle occurred seventeen times out of twenty-two cases on the right side, and congenital hernia was rarely associated.

Mr. J. B. SUTTON showed the Skeleton of a Baboon affected with Rickets; it was admitted into the Zoological Gardens when two months old, fed on fruits and nuts instead of milk, and died in four months. The viscera were not preserved, but the skeleton showed decided signs of rickets. The epiphyseal cartilages were enlarged; that of the femur was ten millimetres instead of one. There were three layers: 1. Normal cartilage. 2. Longitudinal rows of cells. 3. Imperfect ossification enclosing cartilage cells. The tibiae were bowed and very soft. The periosteum thick and succulent. The skull was six millimetres thick, soft and spongy. In another specimen that he found in the museum the skull was twelve millimetres thick. In answer to Dr. Buchanan, he said that dentition was not affected.

Dr. HADDEN showed Microscopical Sections of the Cord in Canine Chorea, in which disease there are rapid contractions of the muscles, as if under the influence of the interrupted current, the disease resembled spasmodic torticollis more than human chorea; it generally followed distemper, and was fatal. Like the cases described by Drs. Gowers and Sankey, there were masses of leucocytes scattered irregularly through the cord, but while in their cases these cells were in the white matter, in his they were among the grey matter, distended capillaries could usually be seen. The appearances were suggestive of an early stage of disseminated sclerosis, and, as they were not constant, were probably secondary, perhaps due to over-action.

Dr. PYE SMITH showed the fresh organs in a case of Colloid Cancer in a man aged sixty years. His first symptoms were cough and pain in the leg, but there was no tumour felt; but later on a small tumour was detected in the region of the liver, and he had pain in the course of the sciatic nerve, and the diagnosis of retro-peritoneal cancer was made. There was no vomiting or hæmatemesis. Post mortem there was no cancer of the liver, but it was simulated by a part of the retro-peritoneal tumour. A very large cancer affected the posterior wall of the stomach, projecting into it, but united to the cancer behind; another tumour projected into the duodenum. There were a few secondary nodules in the liver, while the lung was studded with pea-sized nodules. The microscopical characters were those of colloid cancer, the paucity of vessels accounting for the absence of hæmorrhage during life.

Dr. FREDERICK TAYLOR showed the Heart in a case of Ulcerative Endocarditis. A man, aged twenty-six, had had rheumatic fever, at the age of fifteen, with some cardiac complication. Five months ago he had shortness of breath and wasted. For the last six weeks he had had oedema of the feet. When admitted he had general anasarca, and looked as if suffering from renal disease. There was marked pyrexia and a double aortic murmur, tenderness over the spleen, and the urine was abundant and highly albuminous. Ulcerative endocarditis was diagnosed. Post mortem both aortic and mitral valves were affected with old and recent disease—viz., induration and ulceration. The left ventricle was dilated and hypertrophied. The spleen had several embolic infarcts. The kidneys showed cloudy swelling, and the capsule was slightly adherent in one part. The question was whether the kidney affection was primary or dependent upon the endocarditis? Dr. Taylor thought it was due to the endocarditis, as similar conditions had been observed in other cases.

The card specimens were Thrombus in the Left Common Iliac, by Dr. Kingston Fowler, and Congenital Malformation of the Heart, by Dr. Turner.

### MEDICAL SOCIETY OF LONDON.

*Osteitis Deformans.—Ammonia, Chloroform, and Ammoniated Chloroform as Antiseptics.—Cases of Nephrectomy.*

A MEETING of this Society was held on the 13th inst., Mr. F. Mason, President, in the chair.

Mr. WALSHAM showed a case of Osteitis Deformans (Paget) in a man, aged fifty-five. The affection of the right leg had been noticed for about five years. The left leg was affected shortly after. The right and left femora, the right radius, and the right clavicle enlarged in the order given about three years later. During the last twelve months the skull had increased in size, and the spine began

to bend. His height had been reduced from 5 ft. 7½ in. to 5 ft. 5½ in. during the last two years. He had previously enjoyed excellent health, and had been free from syphilis, gout, rheumatism, and injury to the bones. One sister had died of phthisis, and another of cancer of the uterus.—The PRESIDENT asked whether there was any defect of intellect. Mr. NOBLE SMITH inquired whether the urine contained sugar. In a case of a lady, sixty-one years old, he had pursued a tonic treatment in view of defective nutrition.—Dr. ROUTH had seen a similar case twelve years ago; the anterior portion of the cervical spine being chiefly affected. The patient was an anæmic and ill-nourished child, and death was caused by choking. Defective nutrition seemed to underlie these cases.—Mr. WALSHAM, in reply, said that the man's intellect was unaffected. The urine had been examined for albumen, but none was present. Iodide of potassium had been given without effect.

Dr. RICHARDSON read a paper on Ammonia, Chloroform, and Ammoniated Chloroform as Antiseptics. The author first recalled attention to his original paper in 1850, on the Antiseptic properties of Gases. He had shown that various gases and vapours, including arseniuretted hydrogen gas and chloroform vapour, acted as antiseptics on fresh animal structures, together with many other aeriform and vaporous agents. He showed two small specimens of lung which were shown in 1850 in illustration of the antiseptic powers of chloroform vapour. The specimens had remained in their bottles untouched for over thirty-two years, and were still well preserved. He next referred to a paper he had read in 1862 on the antiseptic properties of ammonia, in which he had shown that the vapour of ammonia was one of the most perfect of antiseptics. In further demonstration Dr. Richardson exhibited a specimen of blood which had been drawn from a sheep's neck into an ammoniated atmosphere in April, 1862. It had been enclosed in a well-corked bottle for more than twenty years. It was still perfectly fresh and fluid, and although its microscopical characters were changed it could be made to undergo coagulation on displacement of the ammonia, so that it still exhibited what John Hunter would have called "the final act of life." Proceeding to his present research, the author said that since his last paper he had continued to use ammonia vapour as the antiseptic most convenient, and he had improved upon it in two ways. 1. When a structure to be preserved contained a great deal of fat it was apt, after a few weeks, to become saponified, by which its character was changed. To avoid such change he had used what he called ammoniated chloroform, which was simply chloroform and ammonia vapour combined. By this means much less ammonia was required, and the saponifying process was prevented. 2. It was sometimes important to preserve the colour of a substance; to effect this the bottle containing the specimen was charged with common coal gas, as well as with the vapour of chloroform. The coal gas contained sufficient carbonic oxide to maintain the colour. Specimens of the heart, kidney, spleen, and the viscera of birds were shown, preserved in these various ways. The advantages were as follows:—1. In making a post-mortem the operator had simply to take with him a jar or bottle well stoppered and ready charged with antiseptic vapour. Into this gas drop the specimens, close them down, and keep them for days, or even weeks. 2. In some forensic cases specimens might be retained in pure ammonia or chloroform vapour in a perfectly sound state during a long investigation. 3. The antiseptic results obtained indicated certain uses of ammoniated chloroform in diseases attended with rapid putrefactive change.—In reply to questions from the President and Dr. Routh, Dr. RICHARDSON said that chloroform would only take up a certain small proportion of ammonia. The solution should be used concentrated. In the case of sore-throat it was administered by inhalation. He feared it would be impossible to use the preparation on a large scale so as to preserve whole bodies. He had it tried on sheep and failed, owing to the gases destroying the tissues. Chloride of zinc and spirit embalmed a body perfectly, but made it too hard for dissection.

Mr. KNOWSLEY THORNTON read notes of three successful cases of Nephrectomy by Abdominal Section. The first case was that of a child seven years old, in whom the left kidney was removed by median abdominal section for hydro-nephrosis, which was probably congenital, as the ureter was only represented by a small fibrous cord. The child made an excellent recovery, and is now strong and well-developed; before the operation she was delicate and puny. The second

case was that of a woman aged twenty-six, who dated her illness from her second and last pregnancy. The kidney was much enlarged. The patient was almost in a dying state when admitted into the Samaritan Hospital in February, 1882. Mr. Thornton first operated through the loin, but failed to find by this exploration the cause of the trouble. She improved for a time, but soon relapsed, and he removed the kidney by lateral abdominal section (incision of Langenbüch), and then found it to contain a large number of small calculi or concretions. The bladder end of the ureter was tied and brought out of the wound at its lower angle—an important precaution, as this portion of the ureter was generally diseased and putrid in its interior. The patient made an excellent recovery, and in a letter just received she states that her health is good, and the urine clear and natural. The third case was that of a woman fifty-eight years old who had been known to have had suppuration of the kidney for sixteen years. The kidney had been aspirated several times without relief, and Mr. Thornton decided to remove it by Langenbüch's incision. The operation was exceedingly difficult owing to the great obesity of the patient and the extensive adhesions. The sac into which the kidney had been converted weighed after removal  $4\frac{1}{2}$  lb., and it contained twenty pints of pus. The patient made a rapid and perfect recovery without fever, the only complication being some bronchitis, which was present before the operation, and became more acute for two or three days afterwards. Mr. B. Morison, of Canonbury, reports her present condition as satisfactory. The cause of the mischief was found to be a very small umbrella-shaped calculus, of which the handle was fixed in the opening of the ureter. All the operations were performed under strict Listerian principles, and to this Mr. Thornton attributed in great part the even and rapid recovery of the patients. He pointed out the great advantages of the lateral abdominal incision over the median or lumbar section, and expressed his belief that it could be the operation of the future in nephrectomy. He drew special attention to his method of treating the ureter in these cases, as he thought it of great importance. He considered that these cases emphasised the fact already demonstrated by his ovariectomy practice, that under antiseptic conditions the peritoneum can dispose of considerable quantities of effused material without the aid of the drainage-tube, and without constitutional disturbance, even after the removal of so important an organ as the kidney. The kidney could be more safely and thoroughly explored by Langenbüch's incision under antiseptic management than by the lumbar incision.—Dr. RICHARDSON remarked that the use of iodine, which was an oxidising agent, destructive of putrefactive products and not a germicide, could hardly be considered as an instance of Listerism.—Mr. H. MORRIS thought the cases did not bear on the comparison between the merits of nephrectomy and nephrotomy. All these cases were clearly cases for nephrectomy; but in others nephrotomy was the proper course to pursue. In the third case an early exploratory incision might have obviated the necessity for nephrectomy. In the second case, were the small black concretions really calculi or concretions of pus and blood? He had lately made an exploratory incision in the case of a man who had since passed a small calculus. A second exploratory incision failed to reveal a stone; but he believed that one was present; and possibly nephrectomy might be required at a later date. No especial antiseptic treatment was employed in that case, but cotton-wool dressings were used. The wound closed with remarkable rapidity, as it did in a previous similar case of his. He alluded to cases where relief had followed nephrotomy, though no stone had been found, and thought that in these cases the affection was an unduly mobile kidney, which became fixed by adhesions resulting from the operation.—Mr. THORNTON, in reply to the President, said he considered silk ligatures more convenient than, and as easily made antiseptic as, catgut. He did not deny that good results might be obtained without antiseptics, but still he held that better results followed their use. Thus he was able to close his wounds without resorting to drainage. He used iodine when he wished to destroy the products of putrefaction; carbolic acid to prevent putrefaction. He did not intend to deny the utility of nephrotomy, but merely to point out that it was not applicable to these three cases. So far as examination had yet gone the calculi contained crystals of oxalate of lime; their outer coating was probably blood.

## WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this Society was held on Friday, Nov. 3rd, and was devoted to clinical cases. Dr. Hart Vinen, President, was in the chair, and some forty-five members were present. The principal feature of the evening was the exhibition of three cases of Charcot's joint disease.

The first case was shown by Dr. ATKINSON. Besides the usual phenomena of locomotor ataxy, the left shoulder-joint was seriously affected. Some three months after the first symptoms were manifested this joint became swollen till it measured thirty-nine inches in circumference, without any pain or inflammation. At that time (some ten years after) the joint was not enlarged, but there was marked prominence of the acromion process and flattening of the deltoid, and on examination the head of the humerus was distinctly absent, having been entirely worn away, so that the arm could be thrown about in any direction, as if it were a flail. Dr. Atkinson said that the pathology of the joint affection appeared to be some degeneration or disturbance of the trophic nerves supplying the bone leading to the defective nutrition of the osseous tissue, and this might also cause the spontaneous fractures described by Dr. Weir Mitchell as sometimes happening in patients with this disease.

Mr. EDWARDS, in bringing forward the second case, said that here too the left shoulder was the special joint affected. When the patient first came under his notice some twelve months ago there was a large effusion under the pectoral muscles (not in the joint itself), which was said to have come suddenly a few days before after lifting a weight; he at first thought it must be a hæmatoma, and aspirated it, drawing off some ounces of reddish fluid. Soon after the swelling recurred in the joint itself, in moving which distinct crepitation could be felt, and the head of the humerus could be easily dislocated, showing that the head of the bone was partially absorbed. With regard to other symptoms, the patient had experienced the "lightning pains," his pupils were contracted unequally, and this patellar tendon-reflex was modified, but not absent.

Mr. KEETLEY exhibited the third case, in which the symptoms of ataxia as well as joint affection were well marked. He remembered seeing Mr. Edwards' case before and thought then that there was no ataxia present, but was not aware if further symptoms had been developed since.

A discussion followed in which Dr. THUDICHUM said that locomotor ataxia was accompanied with a change in the nervous centres termed amyloid (first described by Virchow). Granules were deposited, which after treatment with dilute sulphuric acid and iodine became blue and appeared like iodised wheat-starch granules. It had been said that amyloid matter was albuminous, but that was erroneous. Some amyloid is a starch-like body, and no doubt derived from the decomposition of some of the cerebri bodies, of which the brain and nerve tissues contained more than 4 per cent. This decomposition set free a sugar cerebrin, all of which can be reduced by losses of water to the amyloid matter. The deposition of this matter in any part of the nerve tissue, particularly the spinal marrow, produced all the varied symptoms shown in these cases.

Mr. POTTER next showed a patient, aged sixty-six, who, three years ago, whilst engaged as a labourer, was struck on the occiput by a falling wall, and the cervical spine was forcibly flexed. He was rendered unconscious for two days, but indistinctly remembered some one pulling upon the head and twisting it from side to side. Loss of power and sensation of the right arm and leg was noticed by the man when consciousness returned. He kept his bed for four months, an immovable apparatus for the head and neck being applied. One month after the injury the neck was noticed to be swollen, and increased till one year ago. No history of syphilis or rheumatic arthritis. A swelling in the median line at the back of the neck, extending from one inch below the external occipital protuberance to the sixth cervical spinous process, measuring about four inches in diameter. The trapezii appeared to be incorporated with the swelling on each side. It was hard, dense, with no discolouration, not tender on pressure, and with no evidence of deep fluctuation. The manubrium sterni and upper three costal cartilages and larynx were abnormally prominent; the chin almost touched the sternum. The posterior boundary of the pharynx could hardly be reached with the tip of the finger.

The patient complained occasionally of dysphagia and dull aching pain in the swelling. Mr. Potter thought the nature of the tumour obscure, the history, however, tended to show that the swelling was due to callus, which, in this case, was exuberant, owing to the movements of the neck being difficult to restrain. Whether the spinous processes with a portion of the laminae were fractured without much interference with the cord and nerves it was difficult to determine.—Mr. KEETLEY said that after careful examination of the case he could not help thinking that the patient's injury had been rather under-estimated. It appeared to him that there was a general bending backwards of the cervical region, and that the bodies of the vertebrae had been forcibly compressed, leading to fracture; the deformity was owing to a condition similar to that met with in Pott's curvature of the spine.—Mr. POTTER, in reply, said although this was possibly the case, the absence of callus deposited on the anterior parts of the bodies was a fact to be borne in mind.

Mr. LUNN exhibited the Brain of a patient who had died after a third attack of Apoplexy. The case first came under his notice in the second attack, which was one of right hemiplegia, and aphasia, and from these partial recovery, when the third seizure took place. It was observed that the temperature rose from the commencement of the seizure till death from 99° to 106° F., and after death there was a further rise to 108° in the rectum. Mr. Lunn had noticed this rise in temperature in three other cases of apoplexy. On examining the brain, the right ventricle was found distended with a dark soft clot and fluid blood, and the optic thalamus was extensively lacerated. On cutting through the left corpus striatum, a cyst about the size of a walnut, lined by a smooth yellowish-brown membrane, and filled with clear yellowish fluid, was found.

Dr. CLIPPINGDALE brought forward a case of Spontaneous Dislocation of the Sternal end of the Clavicle consequent upon lateral spinal curvature, due to dislocation of the hip, and observed that he could find no similar case on record, and only one case of spontaneous dislocation of the sternal end of the clavicle.

Mr. KEETLEY lastly showed a case of Arterial Embolism. When the patient was admitted into the hospital in the month of August, pulsation could be felt in both external iliacs, and in the right but not in the left femoral artery; strongly in the right tibia, feebly in the left. In the situation of the left common femoral was a slight swelling tender to touch. Temperature in both legs about the same; no signs of cardiac disease; had shortly before admission been so "low-spirited" as to lead his friends to fear an attempt at suicide. He was put on iodide of potassium (ten grains) and aromatic spirit of ammonia (half a drachm) three times a day. He steadily improved; pulsation gradually returned in the left femoral and grew strong in the tibiae, while the tenderness over the common femoral diminished; but the œdema of the left leg, which had at first been scarcely perceptible, increased considerably till the difference in measurement was two inches. His spirits also brightened up, and he felt quite well, strong, and cheerful.—Dr. POPE asked if the patient were in the habit of flexing his leg.—Mr. LLOYD also wished to know whether there had been typhoid symptoms, or whether the rectum were loaded.—Mr. KEETLEY answered the last two questions in the negative, and said that the man's employment was that of a machinist.

ACADEMY OF MEDICINE IN IRELAND. — At a meeting held on the 18th inst. the following office-bearers were elected:—President: John T. Banks. General Secretary: W. Thomson. General Treasurer: R. McDonnell. Medical Section:—President: William Moore. Council: S. Gordon, H. Kennedy, T. W. Grimshaw, J. W. Moore, J. Hawtrey Benson, J. Magee Finny, Christopher Nixon, C. Cameron, R. A. Hayes, and Alex. Nixon Montgomery. Obstetrical Section:—President: J. Denham. Council: G. Johnston, Lombe Atthill, A. V. Macan, T. M. Madden, H. Macnaughton Jones, Fleetwood Churchill, R. D. Purefoy, W. Cox Neville, Wm. J. Smyly, and John R. Kirkpatrick. Surgical Section:—President: John K. Barton. Council: W. Colles, H. Gray Croly, E. Hamilton, A. H. Jacob, E. D. Mapother, E. Stamer O'Grady, George H. Porter, William Stokes, William Ireland Wheeler, W. T. Stoker. Pathological Section:—President: John M. Purser. Council: Robert McDonnell, A. W. Foot, A. H. Corley, T. E. Little, G. F. Duffey, C. Coppinger, John B. Story, P. S. Abraham, Walter Smith, and Edward H. Bennett.

## BANQUET TO THE MEDICAL OFFICERS OF THE EGYPTIAN EXPEDITION.

ON Tuesday evening last a banquet of welcome was given at Willis's Rooms to the medical officers of the Egyptian Expedition. About two hundred and seventy persons were present, comprising many of the most distinguished members of the profession. The chair was occupied by Sir Wm. Jenner. It was expected that the Duke of Cambridge, Sir Garnet Wolseley, and Mr. Childers would have been present, but the two former were prevented by a command to dine at Windsor on the same evening, and Mr. Childers by the state of his health. His Royal Highness, in a letter to Sir Wm. Jenner, said, "I should gladly have availed myself of the opportunity of showing my interest in the cordial support of the medical department of the army and the medical profession at large, for I am well aware how closely and intimately our mutual professions are connected, and how impossible it is for the army to exist without the steadfast aid of our medical friends. Had I been present, I should certainly have assured the medical officers of the army that I highly appreciate their valuable aid and good work done during the recent short but trying campaign." Sir Garnet Wolseley wrote—"It is a sad disappointment that I am thus prevented from having the pleasure of taking part in an entertainment intended to do honour to those whose services and whose devotion to their military duties are so highly appreciated by the army. There may be diversity of opinion as to the value of our military medical system of administration, but all who are acquainted with the work done by our surgeons in the field will, I think, freely admit that individually none are more devoted to their duty than those who are to be your guests next Tuesday." Mr. Childers, in his letter, said—"I should have especially wished to do honour, as far as in me lay, to the medical officers who have served in Egypt with so much distinction and ability."

After the customary loyal toasts,

Sir JAMES PAGET proposed "The Navy, Army, and Auxiliary Forces." In the course of his remarks, he said that one could not but be reminded of the degree in which of late years science had interwoven itself with war. Chemical and scientific skill was applied to the productions of the materials of warfare, and victory seemed to depend not much more upon the bravery of the men than upon scientific skill, in which the medical profession had their full share. (Applause.) They were still called surgeons, and it was not likely that he should desire that title to be changed, for he was proud to believe that surgery included the whole of the medical and many other sciences. (Applause and laughter.) The members of the Medical Department, whom they were then expressly honouring, brought to their task an amount of scientific knowledge such as very few possessed; they were not surgeons alone—they were physicians and sanitarians. The Department for a long time past could boast of their relations with men of science. Professor Huxley, who had honoured them with his presence, Joseph Hooker, Spencer Wells, and George Gulliver, all showed what men in the Medical Department of the services could do. Long before, they were, indeed, among the leading sanitarians of the time, but now all science was fairly combined in them, and civilians were bound to admit that it would be very difficult to find any body among themselves who could with so great skill and force, and with such advantage to the country, show themselves masters of surgery, medicine and sanitary science. He would not anticipate the next toast by speaking of the works done by those who had served in the late expedition, but at least he might refer to two—Director-Generals Crawford and Reid—as brilliant examples. (Loud applause.) They were all proud to be brought into relation with the bravery, courage, self-denial, and perfect and complete endurance for their country's good, which the members of the Medical Department had shown in time of war. There were men amongst them wearing the Victoria Cross; they could tell tales of men who had been in succession brave soldiers, fighting as soldiers for their own lives and the lives of their comrades, and then men of science and perfect

humanity working for the relief of human suffering. They were glad of an occasion of that kind when those engaged in civil practice might show how entirely, how heartily, they hoped to be always reckoned as of one body with the men who belonged to Her Majesty's services. (Applause.)

The toast was coupled with the names of the Earl of Morley and Mr. Campbell-Bannerman.

EARL MORLEY, in responding to the toast, referred to the committee, of which he is chairman, for inquiring into the general medical arrangements of the army. The object of the committee, he said, was principally directed to the improvement of the organisation of the Army Hospital Corps. The Secretary of State, at the conclusion of the present campaign, thought that a fit opportunity presented itself of utilising the experience gained in that campaign. In no sense whatever was it intended to inquire into the conduct of individuals or of the Department generally. (Cheers.) The desire was to sift all the evidence that could be obtained as to the results of the present organisation. He was sure that evidence would be freely given from all quarters, and that no evidence would be refused that would throw any light upon the subject. The difficulties of transporting a large expedition to such a distance were so enormous that it was absolutely impossible that at certain early periods some things might not be missing. He had heard from many officers of high distinction of the zeal and untiring energy and devotion exhibited by the officers of the Medical Department during the campaign. (Applause.) They all knew that there was no other profession which so thoroughly called into exercise the qualities of self-sacrifice and self-denial, which had been so largely exhibited by those gentlemen.

MR. CAMPBELL-BANNERMAN, M.P., also responded to the toast, and expressed, on the part of himself and his colleagues of the Admiralty, his appreciation of the services of the Medical Department.

THE CHAIRMAN here announced that a telegram had just been received from the members of the Berlin Army Medical Society, then sitting, sending greetings to their brethren at the banquet. He also intimated that a reply would be immediately forwarded by telegram. The Chairman then proposed, "The Medical Officers of the Egyptian Expedition." He said, "Gentlemen, I owe some apology for occupying this chair. (No, no.) When the subject of this banquet first came under my consideration I was most anxious that a surgeon should occupy the chair. I felt that the army and navy surgeons had, in some measure, a right to have a surgeon in the chair, and I spoke to him who may be styled the Chrysostom of medical orators, the man with the golden mouth, and he with his golden eloquence beguiled me and told me that it was rather the duty of a physician, inasmuch as the duties of our medical officers were more medical than surgical. (Oh, oh, and laughter.) He told me, and it was quite true, that 7039 men had passed through the hospitals in Egypt up to the 8th of November, and that of that number only 463 were surgical cases. He also urged upon me, and this had weight with me, that as I was president of the first medical college or corporation in the kingdom, it was my duty to do what I could to do honour to the medical officers returning from this expedition. (Cheers.) I therefore felt that, although I could not lay claim to his eloquence, my halting words, from the position I held, would have some weight with you. Sir James Paget has told us that medical surgery involves everything. It may be so, but I should be very sorry to allow some of my medical friends in the College of Physicians to cut off my leg, and I think he would look twice at some of his surgical friends before he allowed them to treat him for a bad pneumonia. In England, the two branches are to a great extent distinct, and Sir James Paget's argument therefore had weight with me. But there is another department of medicine which is hardly surgical, I mean preventive medicine, sanitary science, and I felt this belonged especially to the physician. It is physicians who teach it, and not surgeons; it is physicians who founded it, and not surgeons. Now preventive medicine, sanitary science, does seem to me, in regard to the army, more even than medical skill or medical treatment. I remember stating, after the Crimean war, to some of my medical friends that if, being ill with fever, I had my choice of being placed in a tent with a jug of water beside me, and a little food such as I could take, I would rather be in the tent with the free air blowing around me—in the best sanitary condition—than in some of the hospitals I had read of, even if I had a

whole college of physicians to treat me. (Laughter.) Our army is still decimated with disease—in Egypt I mean—and was so from the beginning; and this disease, if it is to be met at all, must be prevented by sanitary arrangements. The army will be weakened in a short time if disease continues to make the progress that it has made there. You may ask me if I attribute to the medical officers any want of sanitary knowledge, or of zeal in putting sanitary laws in force. Not at all. In this great metropolis, and in this country, where the powers of civil engineering are at our disposal, where sanitary arrangements can be conducted with precision, where the analyst tests the water and publishes his tests week after week, where the analyst tests the milk and inspects dairies, we find, nevertheless, epidemics of typhoid, we find the subtle germs eluding the most carefully-planned schemes for their obliteration. What, then, must it have been in the East? where dead bodies infected the water, where thirsty men were fain to drink although the drink was death. I say that no sanitary arrangements could have prevented these terrible disasters. Something has been said of the organisation of the hospitals. I am old enough to have witnessed an epidemic of cholera in this country in which patients were thrust into large hospitals, supplied with nurses, with medical staffs and medical students, and I witnessed (because it came suddenly upon them) the confusion and upset of all previous arrangements, and I can, therefore, fully understand that in the East, where they had comparatively few officers, where those officers had, I am sorry to say, other functions than their medical functions to perform—I say I can understand (though I do not know that it was the case) that a certain amount of confusion might have entered into the arrangements of the hospital for a time. Then, again, I am old enough to remember that if the medical officers deviated one letter from the law—if they purchased this or that which they thought was for the good of the patients, it was disallowed unless it was properly ordered. It might be some trifling thing that would only cost 2*d.*; but then, it was said, that 2*d.* had to be multiplied, perhaps, by 150, and the medical officer's pay was not sufficient to enable him to order it, because it would come to a considerable amount. Then the surgeon was called upon to operate when shot and shell were dropping around him, and one distinguished officer, Surgeon-Major George Shaw, whose name should ever be mentioned with honour, fell dead at his post, pierced through the head with a bullet. Now, to preserve a cool head and steady hand under such circumstances indicated a very considerable devotion, and mental power, and training, and I say that all honour should be rendered to those who conducted themselves as medical officers in that expedition under such trying circumstances. None but the medical profession can appreciate all the difficulties and trials that you had to undergo, and none but your profession can judge of the skill and judgment that you displayed. This is a representative assembly; for here we have Oxford sending us its Regius Professor of Medicine, Cambridge its most distinguished surgeon, and we have also amongst us the most accomplished graduates of the University of London. The President of the College of Surgeons and the ex-President of the College of Physicians are with us, with all the most celebrated Fellows of the two Colleges. The most renowned practitioners, in the large sense of medicine, surgery, and midwifery, are here to-night. And why? To express their thorough conviction that you did your duty. (Loud cheers.) It may seem faint praise to say that you did your duty; but remember what it is to do one's duty. It is to bring to bear on the work in hand the whole of your physical power, all your mental and all your moral power; and when the medical profession, in such a representative assembly as this, say that they believe you did your duty, that is a sufficient reason why you should receive a hearty welcome. We desire more; we desire to say that you exercised, under trying circumstances, skill and judgment; and we desire to draw closer the ties that unite us, your civil brethren, to you, the members of the same noble profession. I think myself that the medical officers of the army have no greater honour than to belong to our profession. Highly as I respect combatant officers, highly as I respect other professions, I will yield to none in claims for dignity as regards calling in life (cheers); and if we make everyone here feel the same zeal and the same claim to honour in their profession, I am sure we shall reap the reward. We wish our brethren to feel that we, the civil members of the profession

thoroughly sympathise with them in all their trials and difficulties; that we are one with them—one in their hopes and in their aspirations. I trust, then, that you will drink, with all honour, the health of the medical officers of the army and the navy who have served in Egypt. (Loud cheers.)

Staff Surgeon BELL (in the absence of Staff Surgeon Mahon) briefly acknowledged the toast, and bore testimony to the devotion and self-denial of his brother medical officers in the naval service, and thanked the officers of the Army Medical Department for their hearty co-operation during the late campaign.

Deputy Surgeon-General EKIN responded on behalf of the officers of the Army Medical Department in Egypt. He denied emphatically that there had been any breakdown in the department. On the 27th of July he saw the establishment of the hospital in Alexandria, and he left it capable of accommodating 270 patients. He went on to Ismailia, and there, in consequence of the sudden advance of the troops, everything was not so complete, but there were "stretchers" for many of the patients that were as comfortable as beds; some had no beds, but there was a comfortable dry floor with good ventilation, which was better than sleeping in two or three inches of dust under a tent. During the whole time that he had accompanied the force he had never seen men better looked after, whether on the field or in the hospital. They received every possible care and attention from the medical officers, and he did not think there was a single real case of neglect. The greatest harmony at all times prevailed between the officers of the different services.

Surgeon-General MARSTON also responded to the toast. He said that the arrangements of the Medical Department would have to be tried in a very simple way. The questions would have to be narrowed down to these:—What material had you? What steps did you take to make it accessible? What use did you make of it when you got it? It should be remembered that when they landed the men were instantly moved up to fight, and no sooner were other men landed than they were moved up to the assistance of the first. Then there was a hospital which was called a "base hospital." A base hospital was generally understood to be a general hospital; but it could not be so, because they had no means of making contracts there. They had to depend upon the food which was brought down; but as to medical comforts, beef-tea, milk, soda-water, champagne, claret, &c., there was an abundance of them. It should not be forgotten that there was a strain upon the transport service. Had the transport been there it would have carried the field hospitals, and interposed a break between the fighting army and the so-called base, the base being merely a place for the temporary succour of the wounded who were intended to go on board floating ships. It was his duty to look after the sanitary condition of the force. He had no doubt that there were some cases of privation, many cases of inconvenience, some of discomfort, and a few, perhaps, of apparent hardship, but that there was any actual real hardship suffered he denied. Such hardship would tell upon the health of the wounded, but from August 23rd to September 29th, 2800 wounded men, some of them badly wounded, passed through the hospital, and the percentage of mortality was 6 per month, or, in other words, about one man in 200. (Cheers.) Had the same rate continued for a year it would have amounted to only 6 per cent. of deaths in the hospitals per annum. A charge had been made with respect to the absence of chloroform, but it had been proved that the man in question had had seven drachms of chloroform, and was treated with the greatest care. Six pounds of chloroform were ready at hand at the time the operation was performed. Another statement was that some of the medical officers performed their duties in a perfunctory manner; that one of them asked the patient, "Are you better?" and if the answer was "Better," the medical officer said, "Then why did not you write it on your bedhead ticket?" The fact was that there were no bedhead tickets in the hospital. Another statement was to the effect that pills were taken all round from the same box to the wounded men and dysentery cases. There would have been no harm in that if the pills had been opium, but as a rule, pills being more difficult to prepare than other things, they were only given on the prescript for each individual case. He should like to state a few things that he had himself seen. On the morning of the 13th of September the Surgeon-General and he rode to the battlefield before the battle had taken place. A field hospital had been trans-

ported by the canal, and the flag of the hospital was pitched in the earthworks that had been left by the enemy. The stores were disembarked from the floats on the barges, and twenty-five tents were pitched. The boats were littered with hay to a considerable depth, and planks were put out to form an easy access for the wounded. The wounded began to come in about 7 or 8 o'clock. They were all treated very much in the same way, receiving, according to the gravity of the wound, a small or large dose of opium. The preparations for them were thoroughly prepared at the bottom of the tent, where they were nourished and dressed as well, and as promptly as possible, and, where it was practicable, antiseptically. The opium took effect, and many of the men, even those badly wounded, in less than an hour were asleep. Two hundred wounded Europeans, including seven officers, five of whom were dangerously wounded, were transported in two boats down the canal with an ease that probably had never before been known. About 200 wounded Egyptians were sent by rail. Nearly 400 passed through the hospital at Kassassin. About six cwt. of ice had been brought up by train; most of the men had lumps of ice, and many of them champagne. On the whole, therefore, he thought that it was not a bad day's work. Taking all the circumstances into consideration, he asserted that never had there been a more comprehensive, varied, responsible, or successful medical service rendered in the field. (Loud cheers.)

Deputy Surgeon-General COLVIN SMITH also acknowledged the toast on behalf of the medical officers of the Indian division of the army in Egypt. Happily, he said, everything was prepared in India on a magnificent scale before they left, and there were no shortcomings whatever. The sick-rate was only 15 per cent. for the whole campaign, and the death-rate was nil. Only one man was lost, and in that case death was caused by an injury received on board ship. They had an admirable ambulance corps, which they were able to lend to the Army Medical Department; they also lent men to carry off the wounded at the battle of Tel-el-Kebir, and provided an ambulance corps of ninety-six bearers, who, however, in consequence of being detained upon the railway, did not arrive in time. At Cairo they were able to give 200 dhoolies to carry the sick. He was delighted with his department, consisting as it did of army medical men and Indian medical men, who vied with each other in rendering all possible assistance. (Cheers.)

Mr. ERNEST HART proposed, "The non-Medical Guests."

Mr. H. T. MACPHERSON and Colonel Sir W. O. LANYON briefly responded to the toast.

Director-General Dr. CRAWFORD proposed "The Health of the Executive Committee." Reference, he said, had been made to military medical administration, possibly some would call it medical unification; but there was another form of unification typified by that assembly. It was no small gratification to him to know that the medical officers of the Army, Navy, and the Indian medical service were taken into the ranks of the great medical profession, and received with a brotherhood which was honourable both to the givers and the receivers. It was a proud moment to find themselves standing shoulder to shoulder with the great chiefs of the profession, and it was still prouder for them after the fatigues and anxiety of war, to come home and rest in the bosom of the profession which was proud to do them justice. (Cheers.)

Mr. EASTES briefly acknowledged the toast.

"The Health of the Chairman" was proposed by Mr. SPENCER WELLS, and the toast having been acknowledged by Sir WILLIAM JENNER, the company separated.

## Reviews and Notices of Books.

*A Practical Treatise on Electro-Diagnosis in Diseases of the Nervous System.* By A. HUGHES BENNETT, M.D., Physician to the Hospital for Epilepsy and Paralysis, Regent's-park. London: H. K. Lewis. 1882.

THE remarks recently made by Mr. Lister on the application of certain branches of physics to practical medicine, together with the fact that within the last two years a knowledge of heat, light, and electricity is required from candidates for the licence of the Royal College of Physicians, serve as indications of the recognised importance

to medical men of a knowledge of the physical agents at their disposal. Every efficient physician can bring to his aid such branches of physics as acoustics, optics, and mechanics, but from want of proper knowledge electricity is not utilised as frequently as its importance deserves. Any work therefore which brings before us the uses of electricity as a physical aid to diagnosis must be of interest. Dr. Bennett's treatise on Electro-Diagnosis has supplied a great want. The reader is not only impressed with the importance of this somewhat neglected agent, but he is taught how to use it with almost as little trouble and expense as the use of the ophthalmoscope entails. The author's professed object is to convey to his readers "the means of utilising at the bedside a physical agent of great value in the investigation of an obscure class of diseases." How thoroughly and ably he has performed his task can only be realised by a perusal of the work. Dr. Bennett is careful to point out that electricity alone cannot enable us to form an exact diagnosis of any disease of the nervous system. As the stethoscope enables us to determine certain physical changes in the lungs or heart, so electricity furnishes us with information concerning the anatomical conditions of nerve and muscle, which enables us to complete our diagnosis when combined with a knowledge of the history, symptoms, and other circumstances of the case. Well-marked phenomena are produced by the application of the galvanic and faradaic currents to healthy nerve and muscle, and in disease these results are modified. "It is the careful consideration of the relations which exist between these two states, and the practical advantages which result therefrom, which constitute the art of electro-diagnosis."

A concise and excellent description is given of the apparatus required for electro-diagnosis. The author's element board can be conveniently attached to any battery which does not possess the ordinary accessories. Dr. Bennett's ingenious combined electrode will do much to bring electro-diagnosis into more common use, for the manipulative dexterity necessary in using the ordinary apparatus has deterred many from employing electricity. All the essential accessories are contained in the handle of the electrode, so that the currents can be graduated, alternated, and interrupted by using one hand only. The anatomical knowledge required is shortly stated, and the excellent plates aid in its acquisition.

The chapters on the electrical reactions in health and disease supply knowledge which is absolutely essential for the intelligent use of electricity, and should be read by all who desire to employ it scientifically. The observations on the relative electric excitability of the nerve-trunks, the motor points, and the muscles are worthy of attention. The spinal accessory nerve appears to be the most sensitive to electric irritation. The anterior crural and external popliteal nerves are as nearly as possible equal to the median and facial as regards their electric irritability. Such facts are of use when, for example, both legs are paralysed, and we can derive no information as regards the electric irritability by comparing one leg with the other. The information we desire can, however, be obtained by comparing the nerves of the legs with those of nearly equal irritability in the arms.

A series of cases is given in Chapter VIII. which illustrates the electrical reactions in the different forms of paralysis. The study of this subject is facilitated by the excellent grouping of the various paralysees into those resulting from disease of the brain, of the spinal cord, of the peripheral nerves, and those of doubtful origin. The cases are well chosen, and show that electro-diagnosis is a powerful auxiliary when taken in conjunction with other facts and observations. Dr. Bennett insists most strongly that, "we

must not expect electricity by itself to act as a mysterious power which will give us every information without an inquiry into all the circumstances of the case." In the last chapter examples are given which prove that electricity can often give us information which cannot be arrived at by any other methods of investigation, and that its application is sometimes essential before we can form a complete diagnosis.

The work is calculated to supply the medical profession with scientific information regarding a most important diagnostic agent which has too long been looked upon with mistrust.

#### OUR LIBRARY TABLE.

*Elements of Dental Materia Medica and Therapeutics, with Pharmacopœia.* By JAMES STOCKEN, L.D.S. Eng.; assisted by THOMAS GADDES, L.D.S. Eng. and Edin. Third Edition, 1882. London: J. and A. Churchill, New Burlington-street.—Both dental students and practitioners must be grateful to Mr. Stocken for the very useful manual of which he has produced a third edition. It contains, in most accessible form, information on preparations used in dental surgery, and recipes of all the known remedies for the various forms of toothache, with practical hints as to their application, and on this account it is to be commended especially to the notice of army and navy surgeons, who, under the existing regulations, are compelled often to act the part of dentists when out of the reach of qualified dental-surgeons. The section treating of nitrous oxide gas is most useful, though the part dealing with coma, syncope, and apnoea, is rather involved, and the course to pursue in the event of a foreign body getting into the larynx is not even hinted at. A notable feature of this book is its clear and large type, for which Messrs. Churchill deserve all praise. An index of diseases, with the various remedies numbered according to the page, is an acceptable addition to the volume, which numbering might be carried out with advantage in Section VII., and in the classification of medicines. The literary style of the work is somewhat marred by the frequent occurrence of such solecisms as "strichnia," "rarefication," &c. We also regret to have again to protest against the recommendation of internal remedies by dental surgeons, which this book obviously encourages, and it is to be wished that in future editions the authors may be satisfied with the good work they have done in the large field of dental materia medica without encroaching on the debateable ground of general medicine.

*The Medical Man's Handy Book.* Edited by WILLIAM SHEPPERSON. London: J. and A. Churchill.—This is an unpretentious but very handy little book, giving at a glance, in fifty pages, a list of incompatibles, of poisons and their antidotes, a table of doses, a table showing the strength of the principal pharmacopœial preparations of the chief drugs; a saturation table, a table of solutions for hypodermic use, and a table of spray solutions from Barber. It can be carried easily in the coat-pocket. It claims no merit beyond that of being an accurate and concise compilation, and this claim may be recognised.

*Della Paralisi Regressiva.* GUGLIELMO H. BARLOW, M.D. Versione Italiana pel Dottor VIRGINIO BOMPIANO. Milan: Vallardi. 1882.—Dr. Barlow's clinical study of infantile paralysis has been translated into Italian. By the translator, as well as by Dr. Barlow, the name "regressive paralysis" is preferred to current terms. The task of translation has been very well and faithfully executed, and a few original notes have been added. We are glad to see such careful and thorough English clinical work rendered acceptable to the Italian medical public.

*Magnetism.* By THOMAS P. TREGLOHAN, Head Master of St. James's Science and Art Schools, Keyham, Devonport.

London: Longmans and Co.—A useful little text-book, containing in a small compass a large amount of information on a subject about which, in these days, a great many people are anxious to know something.

*Common British Insects, selected from the typical Beetles, Moths, and Butterflies of Great Britain.* By the Rev. J. G. Wood, M.A. London: Longmans and Co.—This is an abridged account of the above-named insects, more fully treated of in the accomplished author's fascinating volume, "Insects at Home." Beautifully printed and profusely illustrated, this smaller work is just the kind of present to offer to a boy or girl at this season of the year, whilst it is not destitute of attractions to persons of maturer years.

*Letts's Diary for 1883, including the Medical Diary, the Pocket Diary and Almanack, the Office Diary and Almanack, the Rough Diary or Scribbling Journal (two sizes), the Clerical Tablet Diary, and the Housekeeper and Engagement Book.*—All who have used any one or more of this group of useful diaries will welcome their reappearance. By means of them, professional work as well as business operations generally, are greatly facilitated. Indeed, to those who have become accustomed to their aid these diaries, or some of them, are simply indispensable.

*Our Happy Family, being the Little Folks' Annual for 1883, and Cassell's Illustrated Almanac, 1883* (Cassell, Petter, Galpin and Co., London), are beautiful specimens of the arts brought into requisition for the production of Christmas books. They certainly do no discredit to the high reputation of the publishing firm from which they are issued.

### THE ALKALINE PICRATE OF POTASH TEST FOR GRAPE SUGAR.

To the Editor of THE LANCET.

SIR,—For the practical application of the test for grape sugar, referred to, and briefly described, in my letter in THE LANCET of November 18th, and for the indication of the precautions to be observed in its use, both as a quantitative and a qualitative test, several details will have to be carefully worked out. One of the most interesting results of the use of this test is the clear indication which it gives of the frequent, if not constant, presence of a trace of sugar in normal urine, a condition asserted as a fact by some high chemical authorities and denied by others. On this point see Dr. Parkes on the Urine (p. 11).

I am indebted to my son, G. Stillingfleet Johnson, the junior demonstrator of chemistry at King's College, for the following contribution to the chemistry of this interesting subject.

I am, Sir, yours obediently,

Savile-row, Nov. 23rd. GEORGE JOHNSON, M.D., F.R.S.

#### *The Picrate of Potash and Caustic Potash Test for Grape Sugar.*

Several precautions are necessary in the use of this test. First, care must be taken not to employ too strong a solution of caustic potash, for picric acid is decomposed by concentrated potash on boiling, ammonia being evolved in abundance, and a dark-brown colour being produced. The liquor potassæ of the British Pharmacopœia does not decompose picric acid when boiled with the crystals. A solution of potassic hydrate, containing 20 grammes KHO to 1 litre of water (nearly 2 per cent.) produces no decomposition when boiled for many minutes with crystals of picric acid; whilst the full effect of Moore's test for grape sugar may be obtained with a solution of this strength. In testing the limit of delicacy of the potash and picrate test, a 2 per cent. solution of caustic potash was therefore uniformly employed. Secondly, it is necessary to avoid the presence of an excess of picrate, on account of the strong colouring effects exhibited by this substance when boiled with excess even of dilute (2 per cent.) potash solution. It was found impossible to detect less than 50 parts of grape sugar in 100,000 parts

of water, when a saturated cold solution of picrate of potash in 2 per cent. caustic potash was boiled with the grape sugar, and the colour produced compared with that obtained by boiling an equal volume of water devoid of grape sugar, mixed with the same volume of the alkaline picrate. The deep colour of the alkaline picrate itself interfered with the delicacy of the test.

By adopting the following method it is possible to detect three parts of grape sugar in 100,000 parts. 0.8 c.c. grape sugar solution (containing 0.0006776 gramme grape sugar) was mixed with 20 c.c. of 2 per cent. potash solution and 0.5 c.c. of a cold saturated solution of picrate of potash. This liquid was boiled for about thirty seconds in a flask. 20 c.c. of 2 per cent. potash solution + 0.5 c.c. of the same picrate of potash solution was boiled for an equal length of time in another glass flask. The two liquids were then transferred to two colourless test-tubes, held vertically over a white porcelain plate in a good light, when that containing the grape sugar was seen to be very slightly, but distinctly, darker than the other. This experiment, by which the limit of delicacy of the test was fixed, will give a sufficient illustration of the general method to be employed, and the precautions necessary in applying this delicate test.

As regards the application of this test to the detection of grape sugar in urine; since it was observed that normal urine gives a slight indication with the alkaline picrate, the interesting question suggested itself whether any other substance present in urine is capable of producing a colouration on boiling with a solution of potash and potassic picrate.

In order to solve this question, if possible, Brücke's method for separating sugar from urine was employed. About half a pint of normal urine, which produced, however, a blood-red colouration with the picrate test, was mixed with four times its volume of absolute alcohol in a glass beaker and filtered. To the clear filtrate was added an alcoholic solution of ten grammes of caustic potash, and the mixture having been well stirred was allowed to stand for four days.

The addition of the alcohol throws down a copious precipitate, consisting of the bulk of the inorganic salts of the urine, which are removed by filtration. The alcoholic potash produces a gradual separation after a day or two of a compound of grape sugar with potassic hydrate, which is insoluble in the alcohol liquor.

A few drops of a reddish oily liquid separated out and a few crystals formed on the sides of the beaker. The clear yellowish liquor was now decanted from the sediment, neutralised with dilute sulphuric acid, filtered and distilled to remove the alcohol. The aqueous residue in the retort, which contains the extractives and other substances, gave no indication of grape sugar with the picrate test; indeed, it became somewhat paler in colour after boiling with the alkaline solution.

The solution in water of the sediment in the beaker, on the other hand, gave the sugar reaction with alkaline picrate very strongly. This solution was now treated with an excess of solution of basic acetate of lead and filtered, to remove the extractive matters; the filtrate was freed from excess of lead by sulphuretted hydrogen and filtration, and the resulting clear solution was concentrated by evaporation. On testing with the alkaline picrate, it still gave distinct indications of the presence of grape sugar, and, on further concentration, also with Fehling's solution. So far, then, the chemical application of this very delicate test seems to confirm Brücke's statement that traces of grape sugar may be detected even in normal urine. Further confirmation of this statement can be obtained only from clinical observation.

G. STILLINGFLEET JOHNSON, F.C.S.

**PRESENTATION.**—The members of the Loyal Albion Lodge of Odd Fellows, Manchester Unity, have presented their surgeon, Dr. Alderson of Hammersmith, with a silver-mounted library inkstand and a collarette, accompanied with an illuminated framed address, in recognition of his valuable services to the Lodge for the past fourteen years.

A CORONER'S jury at Birmingham has returned a verdict of "Wilful murder" against a midwife at Balsall Heath, for the improper use of an instrument for the purpose of procuring abortion, death having resulted from the operation.

# THE LANCET.

LONDON: SATURDAY, NOVEMBER 25, 1892.

WE were unable in our last issue to do more than make brief reference to the Report of the Inspectors of the Local Government Board on their inquiry into the deaths following vaccination at Norwich. It will be recollected that the circumstances attending these deaths, which were alleged to be due to erysipelas, had, in the first instance, been investigated by Dr. AIRY. It had, however, been felt desirable for the purpose of better ascertaining the cause of the disease which had appeared at the vaccination station, that a public inquiry should be held, and with this object Mr. J. J. HENLEY, one of the general inspectors of the Board, was associated with him. At this inquiry the complainants, the guardians, and the public vaccinator, were represented by counsel, and a number of witnesses were examined.

A perusal of the evidence at once shows that from the beginning of the inquiry to its end the main question of the manner in which some of the children attending the station came to be infected by erysipelas was to a great extent lost sight of; and the efforts of those engaged to represent the different "interests" were devoted either to defending the public vaccinator, Dr. GUY, or to proving that vaccination, as such, was responsible for the series of events which had followed the operation. Fortunately the main facts were undisputed, and the history of this sad occurrence can be readily told.

Of thirty-three children who were vaccinated at the Norwich Vaccination Station on June 13th, six were subsequently attacked with erysipelas; while of twenty-eight who had been vaccinated in the previous week, but who had attended at the station on June 13th for the purpose of being inspected, one subsequently developed erysipelas. One other child, who attended at the station for the first time on June 27th, also, at a later period, suffered from the same disease. Thus altogether eight children were affected, of whom four died. These children may be readily divided into two groups—the first consisting of GIRLING, TYLER, THREADKILL, and LAMBERT, who were all attacked with erysipelas in the vaccinated arms—three within twenty-four hours of the operation, and the other, LAMBERT, who had been vaccinated the week previously, within two days of her vesicles being opened on June 13th at the station by Dr. GUY. The second group, consisting of COLISON, WILLSEA, and WORRELL, developed erysipelas a short time after attending at the station for re-inspection, the attendance of COLISON and WILLSEA being on June 20th, that of WORRELL on July 4th. In each child the erysipelas appeared first on some part of the body other than the vaccinated arm. The eighth case, BROWN, is also described as suffering from erythema, appearing a week after re-inspection on June 20th, but as there is some doubt of the nature of this child's illness, it will be well to omit it from further consideration.

It will be seen that interest is chiefly centred in those children who were attacked with erysipelas within a short while of their visit to the station on June 13th. Up to this date no erysipelas had been present there. By June 20th, the date of the subsequent attendance, erysipelas had already attacked four children, one of whom, GIRLING, with the disease upon her, was present at the station on that day, thus affording opportunity for the further extension of the disease.

The four children referred to received lymph from three separate vaccinifers. LAMBERT had, with five other children, been vaccinated on June 6th from lymph taken from SEWELL. None of these had a bad symptom until after the day of inspection, when LAMBERT was the only sufferer. THREADKILL and TYLER were vaccinated from ARMES, who had himself received lymph from SEWELL, the same source as LAMBERT; the lymph from ARMES was also used for the vaccination of two other children, with the result of the failure of vaccination in each case, but with no production of erysipelas. GIRLING was vaccinated from a child named WICKS, and, omitting BROWN already referred to, five other children were successfully vaccinated without injury from the same source. It is obvious that these children must have received their infection on June 13th, and that the erysipelas from which they suffered was not related to any special lymph. Dealing with this part of the subject, the inspectors lay stress upon the fact that on June 13th thirteen children had been successfully vaccinated without harm before the introduction of the unknown cause of the subsequent mischief. "Then come the four children who were vaccinated from PERCY ARMES: two were attacked with erysipelas the same evening and died within a fortnight; in the other two the vaccination was wholly unsuccessful." "It cannot be doubted," continues the report, "that at that moment some poisonous agency came newly into play at the station. We cannot divest our minds of the strong impression that the lymph used in vaccinating those children must have carried with it the elements of disease which they subsequently developed." The possibility of the introduction of erysipelas by some person, perhaps the mother of one of the children concerned, is considered and disallowed; and the possibility that the introduction of pure lymph into a healthy child's arm may produce erysipelas, is naturally rejected. The relation of the appearance of erysipelas in the children vaccinated from ARMES, and to the appearance of the disease in the persons of LAMBERT and GIRLING, is so far recognised that we are told, "In these later cases the illness was probably due in some way which we cannot trace to the same cause which had operated in the earlier cases on this day." But one other possibility is considered and equally rejected by the inspectors—namely, that the use by Dr. GUY of certain ivory points for the transference of lymph from the vacciner to the vaccinee, could have been the means by which septic poison was introduced into the station—points which, it must be remembered, had been previously used for the same purpose, although subsequently cleansed. It is rejected because the inspectors find difficulty in understanding how, on this hypothesis, it could happen that ARMES should escape being infected by the points applied so many times to his vesicles, while two out of our children vaccinated with those points caught erysip-

las, or how the child LAMBERT should be infected in the act of taking its lymph, while the child vaccinated from her should escape; or how GIRLING should be infected while the child WICKS, from whom she was vaccinated, escaped.

Here we are practically left by the inspectors; and but for the memorandum by Dr. BUCHANAN, which he has addressed to the President of the Local Government Board, the mystery would have remained without solution. But the difficulties, experienced by those who conducted the inquiry, soon disappear when the subject comes to be considered by the light which is there brought to bear upon it. Dr. BUCHANAN shows that the assumption of the introduction of a few dirty ivory points in the middle of the sitting on June 13th is sufficient to account for all that afterwards happened. The difficulties of the inspectors in accepting this theory only hold good if the physical characters of the lymph in each child, and the readiness of each point to give up or retain the matter upon it, were in every case alike. As Dr. BUCHANAN shows, it is more than probable that the lymph obtained from the vesicles of the child ARMES was a weak lymph, from the fact that two out of the four children vaccinated from this source developed no vesicles, and, like most weak lymph, would flow readily. Under these circumstances the lymph could easily be removed on dirty points from ARMES' vesicles without infecting him, while when rubbed into the arms of THREADKILL and TYLER the septic matter on the points would be communicated to these children. So again, lymph might have been removed from WICKS without infecting her, while the septic matter on the point would be easily rubbed into GIRLING, vaccinated from her. With regard to LAMBERT the case is different, for she was undoubtedly infected while acting as vaccinator to JOHNSON, who escaped; but here, as the memorandum shows, there is some doubt whether two other children were not also vaccinated from LAMBERT, and no inquiry seems to have been made to learn further what were the effects on these children of their vaccination; or LAMBERT may have been infected by some point one surface only of which was charged with septic matter, while the other was applied to JOHNSON. The suggestion made by Dr. BUCHANAN is itself a probable one, that LAMBERT might be infected by some point which was used for the storage of lymph, and not again employed at the station. This is a greater probability, for lymph for the vaccination of children at the station would almost certainly be taken from LAMBERT before that for storage, and hence the infected point might not be introduced until after the children had been vaccinated, and until much of the lymph had been removed, when a closer contact of the point with the surface of the vesicle would be inevitable. The whole of these considerations appear to have been neglected, and we can only regret that, in view of the important nature of the investigation, more thought was not bestowed upon the relation which seems to have existed between the bad practice of using ivory points for direct vaccination and the introduction of erysipelas into the station.

Dr. AIRY's past work is so well and so favourably known to us that we cannot but sympathise with him in the difficulties of his position in this inquiry. We have previously pointed out that his first investigation, unhindered by the laws of evidence and other technicalities, had already

elicited many points of interest, and there is no doubt that, had the public inquiry been conducted on the same lines, Dr. AIRY would have been better able to have followed up the clue which was then discovered. It was only in the latter investigation that the fact became known that Dr. GUY had not abandoned the habit against which he had been cautioned of using ivory points for arm to arm vaccination, and if the attention of the inspectors had been directed to ascertaining the cause of the erysipelas rather than to listening to complaints against vaccination and to evidence on behalf of Dr. GUY, there is every reason to believe that, with this piece of knowledge in their possession, the result would have been different.

Nevertheless, the main object has been attained; for, read in conjunction with Dr. BUCHANAN's memorandum, an important lesson may be learnt, and the instruction which he proposes to add to those already enjoined upon public vaccinators—viz., never to use an ivory point a second time—will doubtless go far to prevent in the future a repetition of such an accident as that which has occurred at Norwich.

THE reception by the Government of the Deputation which waited on the President and the Vice-President of the Council on Wednesday, requesting the Government as soon as possible to initiate reform of the Medical Licensing System and of the Medical Council on the lines of the Report of the Commission, was very satisfactory. Lord CARLINGFORD—who may be assumed to come somewhat fresh to the subject, considering how recently he has undertaken the duties of Lord President of the Council—showed his interest in the matter by listening most patiently and attentively to the statements of the deputation. Besides, he asked various questions much to the point. Mr. MUNDELLA, too, listened and spoke in earnest. Dr. WATERS of Chester went over the history of the various attempts to amend the composition of the Council and to effect a consolidation of the licensing authorities, and showed how the profession and the British Medical Association had, over and over again, by large votes and largely signed memorials supported such attempts. On essential points of reform there was wonderful unanimity, the only dissentients being, as in all similar cases, the bodies most needing reform. This opposition is most natural, and supplies an argument in favour of change rather than otherwise. Dr. GLOVER spoke with special point on the question of the Scotch opposition. As the holder of a Scotch diploma in Surgery he felt particularly aggrieved by the disparaging remarks made in England as to the inferiority of the examinations of the Scotch Corporations. He thought the holders of such licences had a right to expect from the Government the creation of a central authority above all suspicion, that could and would guarantee the substantial equality of licensing examinations, whether in London, Edinburgh, or Dublin. It is clear that by reducing the licensing authorities from nineteen to three, and by creating a strong council, in which the Corporations shall no longer be predominantly represented, the work of regulating education and of supervising examinations may be much more effectively done than is at present possible. The Scotch Corporations will little consult their dignity or the interest of their licentiates if they continue their opposition

to the only reform that can stop the mouths of detractors and place their diplomas on a level with those of sister Corporations in the other divisions of the kingdom. Dr. GLOVER was equally explicit in speaking as a Graduate of the Edinburgh University. He pointed out that the interests of the Scotch universities had been carefully safeguarded by the Royal Commissioners, who had indeed adopted the terms offered before the Select Committee of the House of Commons by Professor TURNER, Dr. GAIRDNER, and others, and which involve no practical hardship either to Scotch graduates or the universities themselves. It is inconceivable that the Scotch universities should suffer materially if their examinations are accepted in all but the final stage, and the fee charged to their graduates for the licence of the conjoint board be a matter of a five pound note. Under all the circumstances, the Government, which has greatly advanced this question by a Royal Commission inquiry, has only to act with decision on the basis of the Report, and to take the opportunity of dropping a superfluous corporation in each division of the kingdom, to secure the support of the public and the great bulk of the profession.

THE course of the physical development of the human body has often been the subject of investigation, and most of the facts relating to it have been so carefully ascertained that it might seem that there is scarcely room for fresh researches on the subject. The facts of growth have been, however, once more verified, and, we must add, our knowledge of them has been extended by Dr. THOMA, who has described, in a volume of nearly three hundred pages, the observations he has made, which relate to the development not only of the body as a whole, but also of some of its constituent organs and tissue-elements, and thus constitute a very complete account of the subject. The comparison of his own measurements, and those of others, shows that to the usual excess of the body-length and body-weight of males over females, there is an exception between the twelfth and fifteenth year of life. At this period the development of the female equals, or even exceeds, that of the male, an indication of the earlier attainment of puberty in the female sex. Normal growth is not uniform, but presents an increased or lessened activity at different periods of development. The most rapid growth is observed in the last months of foetal life; after birth it gradually becomes slower, until some time between the sixth and ninth year. An acceleration then commences, which becomes most rapid between the thirteenth and sixteenth year, and after this epoch a progressive retardation is observed. The full height is attained at latest by the thirtieth year, but the average weight continues to increase. In later life both lessen. The variations from the average are greatest at the period of most rapid growth, and least when this is slowest. All the phenomena occur earlier in females than in males.

Of the internal organs, chief attention was paid to the heart and the kidneys. The average weight of the heart undergoes the most rapid increase immediately after birth; its rate of growth gradually diminishes, but at puberty it presents a transient acceleration. After forty-five a slight increase in weight occurs, and no doubt, as commonly believed, this increase is the result of degenerative changes in the arterial system. Apart from these special influences the

curve presented by the rate of growth has nearly the same shape as that which indicates the body growth. Like this, also, the chief deviations from the average are met with at the period of most rapid growth, immediately after birth. THOMA has given certain rules for comparing the weight of the heart and body, by which he believes that the existence of hypertrophy can be recognised with certainty even when it is too slight to be detected by ordinary methods of estimation. The rate of growth of the kidneys is nearly the same as that of the heart and the whole body; and the relation borne by the weight of the heart and of the kidneys to that of the whole body is nearly the same throughout life. At all periods of life the weight of the left kidney is greater than that of the right.

Measurements of the larger bloodvessels showed, amongst other facts, that the post-foetal growth is least in the common carotid artery, and greatest in the renal and femoral arteries, while the rate of growth of the subclavian is between these, and nearly corresponds with the aorta and pulmonary artery. These differences correspond with those which exist in the growth of the parts of the body to which the vessels belong. Up to the thirtieth year of life the pulmonary artery is, on the average, a little wider than the commencement of the ascending aorta. From facts which he has ascertained THOMA has formulated many very interesting mathematical conclusions.

Dr. FARQUHARSON, as will be seen from our "Medical Notes in Parliament," did not obtain a satisfactory answer to the question he pressed on the attention of the President of the Local Government Board on the 13th inst. Dr. FARQUHARSON asked whether Mr. DODSON had noticed "the case of *GRUBB v. the Chesterton Board of Guardians*," and the decision and comments of the Cambridge County Court judge thereon; whether the Local Government Board would modify their Consolidated Orders so as to prevent in future the contingency of a district medical officer summoning his board of guardians to pay him his extra fees; and whether he would lay upon the table of the House a copy of the correspondence between Dr. MARTIN O'CONNOR of Charteris, Cambridgeshire, the Local Government Board, and the North Witchford Board of Guardians, Cambridgeshire, relative to the refusal of the latter body to pay a fee claimed by Dr. MARTIN O'CONNOR." To this Mr. DODSON replied that "he had seen the newspaper report of this case, in which a Poor-law medical officer obtained judgment for extra medical fees for attending a poor woman who had met with an accident. In regard to the proposed modification of the general order, it did not appear to him that the Local Government Board could so alter it as to prevent a medical officer taking legal proceedings against a board of guardians for extra medical fees if they declined to pay, or, on the other hand, require the guardians to pay such fees when not legally due. In regard to the correspondence, that would be produced if the hon. member liked to move for it."

This, we take it, constitutes a typical example of the administrative conduct, and aptly illustrates and exemplifies the policy, of "the Board." The question and answer should be carefully studied by medical officers in the service of the Local Government Board, that they may see how attempts to help them are ingeniously frustrated. The Board — which we fondly hoped might, under the rule of Mr. DODSON,

develop into a Ministry of Health—will have nothing to do with any practical difficulty. Medical officers must fight for their extra fees in a court of law if they are to get them. "Extras" are defined in the Consolidated Order, and guardians are empowered to pay them, but the Board will not take upon itself to determine the merits of any claims. If medical officers want to be paid their just charges, small as these are, they must find time and spend money to obtain justice.

It would be interesting to observe how this final rebuff will affect those of our brethren who serve the Mammon of unrighteousness at Whitehall; but it is a foregone conclusion that appointments under the Board will be as keenly contested as ever, let the Board do what it please or may. We honestly believe that if an edict went forth reducing the stipends of medical officers to a modicum of the present paltry rate, and insulting them by fresh impositions, the competition would be as eager as ever for the service, and the work would be done fully as well—in fact the same men would do it. Under these circumstances what possible good is likely to result from protesting and remonstrating? Dr. FARQUHARSON did his best, and it was kindly meant, but he "kicked against the pricks," and the manner in which his just appeal was met is simply a fair specimen of the sort of response all such appeals are likely to elicit.

AMONG the subjects which have been brought prominently to public notice within the last few years, there is perhaps none more deserving attention than the influence of houses in an insanitary condition upon the health of the inmates; and this injurious influence is not to be observed only in the crowded, ill-constructed dwellings inhabited by the poorer classes, or even by those who have the means of living comfortably and under conditions which might be presumed to ensure health, but it is found in active operation in the mansions of the highest and most wealthy. Of this the fatal illness of the Prince Consort, and the long and severe attack of typhoid fever from which the Prince of WALES suffered, are notable public instances. But the leading members of the profession know too well how often serious disease from defective sanitary arrangements occurs in the families of persons occupying splendid mansions in the West-end. The defects are sometimes the result of gross and culpable neglect on the part of the builders or their clerks of works, in such cases, for example, as the omission to open the house-drains into the sewer or to trap the drains, or allowing the soil-pipes to be made with slip-joints instead of being soldered; in other instances they are the result of ignorance on the part of the persons employed, who are not aware of the necessity for careful levelling of the drains, and cutting off all communication between them and the cisterns and sinks. But householders are exposed to these serious risks, not only from defective original construction, but also from the consequences of wear and tear, of accidental damage, and of the destruction caused by rats. It becomes, therefore, a very serious question for pater-familias, when he is changing his residence, how to weigh the probabilities of it proving a healthy one, and after he has occupied it how he may assure himself of the continuance of this satisfactory condition. To send for a builder or a surveyor to inspect the proposed residence by no means

affords a guarantee that the desired object will be attained, for unfortunately there is still a large proportion of these classes who are ignorant of the principles of sanitary science, and who, while they can judge satisfactorily of the condition of the building as regards brick and mortar and timber, the soundness of the walls, floor, or roof, are yet unable to give a correct opinion upon its health requirements. To meet this difficulty, within the last two years several associations and limited companies have been formed with the object of providing for the inspection and supervision of the dwelling-houses of the members and subscribers by a competent staff of well-qualified sanitary officers, surveyors, and engineers. Three such associations have been organised in London and several in the provinces. Subscribers may have their houses carefully and skilfully inspected, the defects in their sanitary condition pointed out, and the necessary alterations and improvements suggested. These, if adopted, may be carried out under the superintendence of the Company's officer, in accordance with an estimate given along with the report. Members are also entitled, so long as they continue their subscription, to have their premises inspected annually, with a view to ascertain that they continue in a satisfactory condition. The advantages arising from such an arrangement are too obvious to require comment. The expense incurred will probably be far more than compensated by the exemption from preventable disease and the satisfactory feeling that every precaution has been taken to preserve the health of the inmates. We believe there are very few houses in London of which the sanitary condition could not be improved and does not require careful supervision, and we therefore strongly recommend the subject to the serious consideration of all heads of families. The injurious effects upon health arising from the very general neglect of even the most obvious sanitary precautions are too common, and far too serious to be overlooked; and we trust the day is not far distant when the preservation of the members of a family from preventable causes of disease will receive as much attention and care as the provision of the more obvious necessities of life.

## Annotations.

"Ne quid nimis."

### THE EXECUTIVE COMMITTEE OF THE MEDICAL COUNCIL.

THIS committee, which largely does the work of the Medical Council, met on November the 10th. Over sixty names which had been erased from the Register under Section 14 of the Medical Act were ordered to be restored on payment of the prescribed five shillings. We cannot too often remind our readers of the necessity to communicate changes of address, and to answer letters of inquiry, if they would escape erasure under this clause. In numerous instances leave was given to antedate studies on the strength of pupilage, or unqualified assistantship. In some instances leave was given to be registered as medical students without passing a preliminary examination. A new preliminary examination was recognised by a decision of the Executive Committee. This is an examination to be established by the Oxford and Cambridge Schools Examination Board to serve in lieu of the ordinary entrance examination to the various professions. A report was read from the College of Pre-

ceptors with important information on the state of preliminary education as tested by the college examination for medical students. Of 223 examined at London, Bristol, Birmingham, or Leeds, 74, or about one-third, passed, and 146 failed to obtain certificates qualifying them for registration as medical students. The secretary says "half the rejected candidates, or a third of the total number examined, were very ignorant, and several had been rejected at previous examinations." We may here observe that the volume of the Minutes of the Council for the present year is now to be had of the printers, and contains much matter of professional and public interest.

#### BANQUET TO THE MEDICAL OFFICERS OF THE EGYPTIAN EXPEDITION.

ON Tuesday last the medical officers who served in the late campaign in Egypt were entertained by the leading members of the profession at a banquet in Willis's Rooms, to welcome them home. Sir W. Jenner, Bart., K.C.B., President of the Royal College of Physicians, was in the chair, supported by Lord Morley, Under-Secretary of State for War, and H. Campbell-Bannerman, M.P., First Secretary to the Admiralty, representing respectively the Army and Navy. Letters were read from H.R.H. the Duke of Cambridge and Sir Garnet Wolseley, expressing their regret at being unable to attend in consequence of having received Her Majesty's commands to dine at Windsor after the ceremony of the distribution of medals to the troops, and from the Secretary of State for War, who was prevented taking part in the entertainment by the state of his health. The meeting was a thoroughly representative one of the profession, there being about two hundred and seventy present, including most of the leading men in civil practice, and about sixty medical officers of the army and navy. During the meeting a telegram was received from the members of the Berlin Army Medical Society conveying their good wishes to the medical officers returned from Egypt, which was at once duly replied to by the chairman. In acknowledging the toast of "The Navy, Army, and Auxiliary Forces," proposed by Sir James Paget, the Earl of Morley and Mr. Campbell-Bannerman both bore testimony to the zeal and untiring energy exhibited by the medical officers throughout the campaign, to the appreciation on the part of both the War Office and the Admiralty of the services they had rendered, and to the desire of the authorities to promote by every means in their power the perfect efficiency of the medical branch of the services. The toast of the evening, "The Medical Officers of the Egyptian Expedition," was proposed in an eloquent speech by the Chairman, who adverted to the difficulties they had successfully encountered, their troubles on sanitary matters, their hospital difficulties, and their surgical trials. The toast was acknowledged on behalf of the Navy by Staff Surgeon Bell, of the Army Medical Department by Deputy Surgeons-General Ekin and Marston, and of the Indian Contingent by Deputy Surgeon-General Colvin Smith. These officers, in their respective addresses, gave some interesting information regarding the difficulties with which they had to contend, the amount of work done, and the satisfactory results, as shown in a very low rate of mortality. It is the first opportunity they have had of answering in public any of the charges brought against them, in some instances in a most unscrupulous and unjustifiable manner. They have drawn attention to the great difficulties under which they laboured, chiefly from the inadequate transport available—a want which they admit was unavoidable under the peculiar circumstances of the campaign, and for which they do not desire to throw blame on any of the other departments, but for the results of which they decline to be held responsible themselves. With regard to the

charge brought against them in connexion with the treatment of the patients in the hospital at Ismailia, which was not really a base hospital, but a depot for the reception of sick and wounded while awaiting embarkation in one of the hospital ships, Colonel Sir Owen Lanyon gave some most important information. Sir Owen stated that, as base commandant, it was his duty to visit the hospital daily, and he had on these occasions always specially inquired whether the men wanted anything. During the whole time he had only two complaints from men lying in contiguous beds badly wounded, one in the jaw, the other in the chest. They stated that they had had nothing to eat for thirty-six hours, which was perfectly true; but he found they had abundance of fluid food—not a bad diet, one would suppose, for such cases. Coming from an officer of Sir Owen Lanyon's standing and experience, this cannot but be regarded as valuable testimony to the satisfactory manner in which that hospital must have been conducted. We have no doubt that many of the other charges will be ascertained by the Committee now inquiring into the working of the Department to be based on equally insufficient grounds. The meeting must have been most gratifying to the medical officers of the Army and Navy, as evincing the warm interest taken in their success and welfare by their brethren in civil life, and will doubtless tend to strengthen the bond already existing between them.

#### "OVER-WORK" AS A HEALTH PRESERVATIVE.

THAT great debating club, the House of Commons, on a recent occasion devoted a little of its evidently superfluous time and energy to the discussion of a very interesting question in physiological psychology—namely, how far the mental and physical toil of tedious sittings carried far into the nights may tend to clearness of judgment, strength of intellect, health, and longevity! The senior member for Northampton, with that originality for which he is remarkable, enunciated as "a statistical fact that those who wished to live long ought to sit up late." Something of the sort has, indeed, been said before in a once popular song, wherein, if we remember aright, it was laid down that "to lengthen your days" the best plan is to "take a few hours from the night;" but Mr. Labouchere is probably the first to commend this method of prolonging life, in all seriousness, to the consideration of the Legislature. In support of his "statistical fact" the hon member instanced the late Lord Palmerston, and the late Lord Russell, and the present Prime Minister. This style of argument reminds one of the ingenious inference once deduced from another "statistical fact"—namely, that the old night-men of London enjoyed an exceedingly low death-rate. It was forgotten that few men engaged in this service until they had survived most other occupations, and given practical proof of their being able to bear very nearly anything. Moreover, the men who spent the night in emptying cesspools, could, if they chose, sleep by day, whereas, as Mr. W. H. Smith pointed out, this privilege is practically denied to the great majority of our legislators, and without exception to the working members of a Government. The senior member for Westminster was amply justified by facts, general as well as statistical, in expressing an opinion that "it would be conducive to the public interests that they should be able to bring a coolness of intellect and a freshness of power to the consideration of the questions that were brought before them." This is, obviously, impossible while the House of Commons sits far into the night; and not only members of this august assembly, but the public interests, suffer in consequence. We will not be so ungracious as to profess our entire sympathy with the view propounded by Mr. O'Donnell, who did not think it of much consequence even if their numbers were thinned by protracted debates! The community at large probably looks at the

matter pretty much in that light. It is, however, for us to say that we are sorry to see the Commons of England sacrificing their health and shortening their lives by a mode of serving their country for which, be it honestly confessed, their country has no preference, and is not grateful. Mr. Cowen was strictly just in his physiological argument; the excessive strain thrown on the strength of even a member with "an iron constitution" not only endangers his health but impairs, if it does not destroy, his "temper"—using the term in its true sense—so that the exercise of a perfect judgment is impossible. No man expects a sleepy and jaded steed to show its paces to advantage; and no reasonable man can believe the brain cerebrates most efficiently after it has been wearied and worried by a long sitting. As a matter of fact, observation, and experience, the great bulk of the more important questions which come for consideration before the Legislature are debated and decided under conditions which render it impossible that the minds at work upon them should be, at their best, in full force and at once acutely active and resilient. This is a very serious reflection for the public. It is not conducive to the interests of the community that its laws should be made and its affairs managed by intellects which are, to use a familiar expression, "pumped out." The brilliancy which sometimes seems to distinguish the House of Commons late in the evening, after its members have returned from dinners and assemblies, is allied to the courage which may be stirred in the mind of a poltroon by a strong glass of brandy-and-water. There is no depth of sagacity in the legislative counsels of the small hours. The speeches delivered at that period of a sitting are like the red fire at the close of a pantomime—they quickly go out in farce. The last hour or two of even a sensational debate is little better than a display of oratorical fireworks, and the division which follows is either a foregone conclusion or a *fiasco*. It is time this question were discussed by the country. It is unreasonable to hope that it will ever be fairly debated in the House of Commons itself. If the mere fact of being able to sit up late at night is to be the principal qualification for Parliamentary honours this ought to be understood. We fancy most citizens would prefer to be governed by legislators and administrators of the greatest intellectual capacity, working under conditions conducive to health and favourable to the exercise of mind-power in its state of highest efficiency.

#### THE REWARDS FOR THE CAMPAIGN IN EGYPT.

It is with much gratification that we observe that the medical officers have come in for a fair share of the promotions and rewards which have been bestowed with a liberal hand in acknowledgment of the services performed in Egypt. And it is still further satisfactory to find that these rewards have not been confined entirely to the senior grades, but that all ranks of the department have been included. The more substantial rewards in the shape of promotion have been as follows: Brigade Surgeons J. A. Marston, M.D., and W. G. N. Manley, V.C., to be Deputy Surgeons General. Surgeons-Major J. S. Comyn, M.B., and B. T. Giraud, M.B., to be Brigade Surgeons. Surgeons-Major, with relative rank of Major, T. F. O'Dwyer, M.D., and Lawrence Corban, M.D., to be Surgeons-Major with the relative rank of Lieutenant-Colonel. Surgeons J. G. Rogers, M.B., and B. R. Connolly to be Surgeons-Major; and Captains of Orderlies D. Pringle and R. T. Osborne to be Honorary Captains. Of the less substantial but not less coveted honorary distinctions the following have been gazetted:—Deputy Surgeon-General J. A. Hanbury, M.B., C.B., has been promoted to be a K.C.B., and has been permitted to accept the second-class order of the Medjidie; Deputy Surgeons-General Colvin Smith, M.D., and J. Ekin, M.B., have been created Companions of the Order of the Bath, and have received the third

class of the Order of the Osmanieh, and Brigade Surgeons W. G. N. Manley, V.C., and J. A. Marston have also had the third class of the Osmanieh conferred on them. Surgeon-Major J. H. Beath and Fleet Surgeon Ingham Murray, R.N., have been made Companions of the Bath, and the former has also received the third class of the Order of the Medjidie. The third class of the order has also been conferred on Brigade Surgeons O. Barnett, C.I.E., E. G. M'Dowell, E. M'Grath, R. W. Jackson, C.B., and Surgeon-Major G. S. Davis; and the fourth class of the Order of the Osmanieh on Surgeons-Major J. D. Edge, G. W. M'Nalty, and W. N. Keefer. We heartily congratulate the medical services upon the distinctions thus conferred on their members, and trust they may long continue to display, alike in war and peace, that zeal and energy which have been marked characteristics of the medical officers in this trying campaign.

#### THE USE OF THE SPECULUM.

THE progress which has been made during the last fifty years in every branch of medical science has been made along a very crooked way; divergencies from the straight path have been long and frequent; errors of various kinds have, one after another, ruled in the schools for more or less protracted periods. At one time most of the diseases of women were referred to the ovaries, at another to inflammation of the uterus, at another to inflammatory ulceration of the neck of the uterus, and at another to so-called displacements of the organ. For many years after the revival of the use of the speculum by Récamier, the great majority of cases of disease of the pelvic organs were claimed as ulcerations of the cervix. This was not unnatural, for the cervix was the only part which could be examined ocularly, or indeed be examined at all. The means for exploring the whole of the pelvis, the ovaries, the body and canal of the uterus had not been discovered, and the consequence naturally was that every case of supposed uterine disease was examined by the speculum. The value of the speculum as a means of diagnosis was, however, greatly over-estimated. Belief in the importance and frequency of inflammatory ulceration of the cervix was rife more than thirty years ago, and for long afterwards, and during this period the necessity of the speculum both for diagnosis and treatment was pretty generally held. There were, however, some who attached no importance to the so-called ulceration, and who brought forward reasons in favour of their views which have convinced gynaecologists generally of the error of the pathology which refers the mass of cases of uterine disease to inflammation of the cervix. With the downfall of this system of uterine pathology the speculum naturally fell into disuse, and when the so-called mechanical school came into existence the use of the instrument as an aid to diagnosis became infinitesimally small. Whether the pathology which has done so much (its best result, perhaps) to discourage the use of the speculum is already on the wane, or is destined to further development, certain it is that the speculum will never be had recourse to for diagnosis with the same frequency as at the period above referred to. For many years, now, the greatest strides in gynaecology have been made in the surgery of the pelvic organs, and the operations devised for the renovation of these organs when injured, or for the supposed improvement of their shape and position, or for the enlargement of constricted or supposed constricted orifices, are numerous; for all these operations the speculum is necessary, and without its aid they cannot be safely carried out. For applications to the mucous membrane of the vagina, also, and for intra-uterine medication, a plan of treatment which is probably destined to greater development than it has hitherto attained, the instrument is indispensable. The means now at our command for

exploring the condition of the pelvic organs are so far superior to the speculum that it forms by no means an important aid in diagnosis, while it is, and always must remain, an indispensable instrument in the local treatment of diseases of the uterus and vagina. —

#### A PAINFUL CASE AT MELBOURNE.

A VERY painful case in its medical bearings has occurred at Melbourne, and been the subject of a coroner's inquest. A Mrs. Stentt, not living with her husband, but with another man, found herself in the fourth or fifth month of pregnancy. On the 4th of August last she went to consult Dr. Barker. Previous to going, according to the testimony of some of the witnesses, she told them she was going to Dr. Barker's to have abortion induced. While in Dr. Barker's surgery she died. He communicated in the first instance with an undertaker and arranged with him for the removal of the body to the undertaker's establishment. He became responsible to the undertaker for the expenses of the funeral and the grave. He saw the city coroner, Dr. Youl, and so far satisfied him as to the case that a permission to bury was accorded without an inquest. He gave a certificate that the deceased died from epilepsy and varicose veins. He also communicated with her friends, but dissuaded them from seeing her, as she was turning black. Under these circumstances, and after a private interview with her husband, the funeral took its course. But there was a slumbering dissatisfaction about the circumstances of the death of Mrs. Stentt, and the coroner at the end of five or six weeks ordered an exhumation and a post-mortem examination. This was made by Dr. H. B. Allen, Mr. Girdlestone, and Dr. Williams. Decomposition of the body had gone far. There were no marks of violence on the external surface. There was, however, a small opening in the skin on the inner side of the right thigh, in close relation with a varicose vein. This might have been a small ulcer during life. There were varicose veins of the legs. The different organs were healthy. The deceased was pregnant to about the fourth or fifth month. "There was an apparent internal wound, through which a probe could be passed upwards about an eighth of an inch under the mucous membrane." The different organs were almost entirely bloodless. There were no stains on the dress. The witnesses all agreed as to the appearance, and in saying that they could not say at that interval what was the cause of death. Dr. Barker was not called to give evidence; but his son was called, who testified that his father called him to see the deceased in the surgery—whom he recognised as having, nine or ten weeks before, been operated on by his father for varicose veins, whom he found fainting, and whom no means could restore to animation. There was no smell, he said, of chloroform. The coroner summed up, and made light of the idea that the internal wound could have caused death. He also thought it natural that a medical man would be anxious to get rid of a dead body, and so have recourse, as Dr. Barker did, to an undertaker. The following verdict was returned: "The jury, having carefully considered the evidence, are of opinion that Mrs. Stentt may have gone to Dr. Barker's with the intention of having abortion procured, but that there is no evidence to show how she came by her death." This verdict did not satisfy public opinion. The Chief Secretary called on Dr. Barker to resign his office as member of the Medical Board and member and chairman of the Board of Visitors to the Metropolitan Lunatic Asylums. To this demand Dr. Barker wrote a long reply defending his conduct. He stated that the deceased came to him asking him to produce abortion. To which he replied, "Certainly not." Whereupon she did not pursue the subject, but in a second or so exclaimed, "I feel very ill—I feel such a fullness in my stomach;" then, almost in the same moment, slid forward

in what he thought a fainting fit, from which she could not be recovered. Dr. Barker alleged that the room in which all this occurred opened into another room by folding doors, which were open, and that in this other room there was at the same time a male patient named Cherry. Cherry said he had heard no noise from the adjacent room, but could not see what was going on. This is, indeed, a most painful case. It is difficult to account for the internal wound, and the reports do not enable us to judge of its locality or its importance. The most unsatisfactory part of this case is, to say the least, the indiscretion of the medical man, and the coroner, in not having the case investigated at the period of death by an inquest. A medical man is always liable to have a patient die in his house, but his attitude should be that of one who courts inquiry. Above all, he should avoid obligations to the undertaker, and seek the co-operation and presence of friends. By taking an opposite course, even with the unaccountable consent of the coroner, he lays the basis of endless suspicion. The result is the more distressing as Dr. Barker is a man of forty years' good standing in Melbourne, and filling several public offices.

#### SCOTTISH LORD RECTORS.

IN view of the proposed Executive Commission to inquire into the changes most desirable in connexion with the working of the Scottish universities, the recent disgraceful conduct of the matriculated students at Edinburgh and Aberdeen, will, by those who wish to see the power of election of the lord rector retained by the students, be deplored. Over and over again scenes sufficiently rowdy have been witnessed when the elect of the students have attempted to discharge the duty of delivering the address which the constituency seems to consider the chief duty of its representative. The lord rector is President of the University Court, which, consisting of the rector, principal, and four assessors, is the court of appeal for the Senatus, and, in a very large measure, is the governing body of the university. He is, with the exception of the chancellor, the head of the university, and during his tenure of office should exercise a large influence in its affairs. It appears strange and unsatisfactory to many, both outside and inside the northern universities, that a body of youths totally unacquainted with the very constitution, apart from the aim and policy of their colleges, should have the opportunity of so frequently making mistakes in the choice of an official of such importance to the best interests of education; while the council, composed chiefly of the graduates, have the right of nominating but one of the assessors to the court. For many years the contest for the rectorship has been entirely political, and usually men known only, or chiefly, in politics have been nominated. Dr. Bain, of Aberdeen, is perhaps, the only lord rector ever elected at that or any other university whose claims were purely academical; and usually the eminent Englishman upon whom the unsought honour is conferred is totally unconnected with, and profoundly ignorant of, if not indifferent to, the views, if such exist, of his constituents. As a rule the part taken by the rector in the work of the university court is extremely small, and it is only towards the close of his term of office that the force of precedent constrains him to satisfy his youthful adorers by the delivery of respectable and perhaps eloquent platitudes, and to offer himself and his friends as targets at which peas meal, hideous sounds, and perhaps blasphemous interruptions can be hurled. A man so singularly of themselves as Dr. Bain, instead of commanding respect and deference from boys who ought to feel proud that such a man is connected with their *alma mater*, is insulted and interrupted so outrageously that he has to take the unprecedented course of handing his address to the reporters.

Remembering the treatment meted out to Lord Rosebery, who might more fitly have lectured his audience on "Decency" than on "Patriotism," we shall be curious to note the reception offered to Mr. Bright at Glasgow in the spring; but recent events, as well as the whole history of rectorial elections, addresses, and neglect of duty, seem to indicate that the time has arrived when such an important official as the lord rector should have a different constituency. At best the election is but a serious interruption to the work of the session; the addresses, with one or two exceptions, such as that of Carlyle at Edinburgh, have been far from memorable; the men chosen have usually had other important duties preventing the due performance of those of this office. The rectors themselves have been distinguished for almost every virtue, except an interest in Scotch universities, while the few who can claim this knowledge and interest have been insulted in a manner even worse than the strangers.

#### THE ROYAL REVIEW AND THE VOLUNTEER AMBULANCE DEPARTMENT.

WITH the approval of the General Officer commanding the Home District and the Director-General of the Army Medical Department, a circular was issued on Thursday, the 16th inst., by Lieutenant Maclure, Hon. Secretary of the Volunteer Ambulance Department, to the medical officers of various Volunteer corps, requesting them, together with trained bearers of their regiments, to muster at Whitehall Yard on Saturday morning, at eleven o'clock, equipped with stretchers, field-companions, and haversacks. Owing to the shortness of the notice given, it was impossible to secure a large muster. Nevertheless, at the hour appointed, Surgeon-Major Harvey Hill, 18th Middlesex R.V., and Surgeon Platt, T.H.R.B., together with forty bearers, were present at the rendezvous; stretchers, water-bottles, field-companions, and splints being served out by Lieutenant Maclure to each of the ten detachments. They were then marched off, and a detachment placed at each of the following stations along the route to be taken by the troops—viz.: 1, Centre of Piccadilly; 2, top of St. James's-street; 3, opposite St. James's Palace; 4, Waterloo-place; 5, Trafalgar-square; 6, Horse Guards; 7, corner of Parliament-street; 8, 9, Birdcage-walk; 10, corner of Buckingham-Palace-road. Where available, the shelters in the middle of the roads were utilised as ambulance stations, and their position was notified by means of a white flag with a red cross. The object of these arrangements was the rendering assistance to any sick or injured members of the troops, Volunteers, or general public. Happily no serious accident occurred, but in eight or nine cases the detachments were enabled to render immediate aid to civilians who were suffering from epilepsy and faintness: in some instances temporary help was sufficient; in others the patients were conveyed home by the bearers. A cleverly prepared map, giving the line of route, position of the different ambulance stations, and nearest hospitals, was provided by Lieutenant Maclure, and supplied to each detachment. The experiment, hastily yet efficiently carried out, was eminently satisfactory, and on this occasion proved a greater boon to the public than to the troops and Volunteers. Such an organisation is at all times necessary when immense bodies of people are collected in the streets, and the presence and ready assistance of these trained bearers on Saturday last proved a great comfort to the few who did suffer, whilst in the event of alarming accidents, only too likely to happen on any similar occasion, their aid would be invaluable. The medical arrangements and command of the entire ambulance force engaged throughout the day were divided between Surgeon-Major Harvey Hill and Surgeon Platt; whilst the bearers were composed of men from the Tower Hamlets Rifle Brigade, 18th Middlesex R.V.,

London Scottish, and other metropolitan corps. The whole of the executive details were ably carried out by Lieutenant Maclure, the Hon. Secretary.

#### PROFESSOR BELL ON THE DETECTION OF METALLIC MASSES IN THE HUMAN BODY.

AT a recent meeting of the American Association for the Advancement of Science, Professor Graham Bell delivered an address on the electrical experiments to determine the location of the bullet in the body of the late President Garfield, and described a completely successful form of induction balance for the detection of metallic masses in the human body. The lecturer recalled the experiments of last year on the wounded President. The results obtained were that the telephone gave a peculiar spluttering sound, which, on the induction balance being passed over the person of the patient, suddenly increased in loudness when it rested on a particular spot. The apparatus was sensitive to the presence of a leaden bullet five inches from it. An area of sound was thus marked out, and the experimenters concluded that the bullet was within it, but subsequent examination proved this to be incorrect. In fact, the area of sound was produced by a steel spring mattress under the President's bed, which had been overlooked by the attendant physicians. The apparatus has been subsequently improved by embedding the two movable coils in paraffin, and adjusting them to silence by a micrometer screw. With this instrument a successful experiment has been performed on the person of Colonel Clayton, who for several years has suffered from the presence of an Enfield bullet, the position of which could not previously be determined; and now, according to Professor Bell, the exact position of a bullet in any part of the human body can be accurately told. A fresh step in the progress of the surgery of gunshot wounds would seem, by the use of this instrument, to be indicated.

#### ENTERIC FEVER AND LEMONADE.

DURING the ten weeks ending September 23rd last a sudden and considerable epidemic of enteric fever affected the urban, and portions of the rural, districts of Evesham. The total number of attacks in the former district were forty-eight, and in the latter district twenty-one; and as many as fifty-one households were invaded in all. The epidemic has been reported on by Mr. G. H. Fosbrooke, medical officer of health for the combined area in which Evesham is situated, and the report, like many of those which have preceded it, affords proof of the care and ability which Mr. Fosbrooke devotes to his duties as health officer. By far the largest incidence of the disease was upon the fortnight ending August 8th, during which period forty-six patients were attacked in the two districts; or, in other words, 62.5 per cent. of the urban cases, and 76.1 per cent. of the rural cases, fell ill during that period. At first sight the patients appeared to have nothing in common which could account for the disease. The houses in which they lived were in many instances several miles apart, the sanitary circumstances of the dwellings varied widely, sewers and water-supply were entirely different, and the milk-supply was derived from several independent sources. It was, however, elicited that one and all of the patients attacked before August 8th, whether residing in the town or in the country, had attended Evesham regatta, and that they had all been present in one special meadow. The circumstances of this meadow had to be very carefully considered, because it was the locality in which two sewer ventilators were placed, and near which were sewage settling tanks. But for reasons given, these conditions could not be identified with the epidemic, and a fresh cause had to be sought. It was then ascertained that of the forty-six persons upon whom the "regatta influence"

had operated thirty-two had certainly, and eleven had at probably, taken water in the form of lemonade, or to a extent in the form of ices, or again, as an admixture with irts, at a certain refreshment stall; and even as regards three remaining patients it could not be said positively t they had not partaken of one or other of the articles in estion. The water, which had certainly been used for ne, and which had probably been resorted to in the case of of the refreshments, was procured from a well which was ated near the meadow, and which was found to be so ously contaminated that it was at once closed under a gisterial order. As confirmatory of the view that the reshments and the disease were related to each other as se and effect, Mr. Fosbrooke cites some interesting details. us, a party of three persons repaired to the meadow nction on the regatta day; two of them partook of lemonade d subsequently developed unmistakable symptoms of teric fever; the third took no such refreshment and together escaped. The only point in Mr. Fosbrooke's reason- g which appears to be at all inconclusive is the circum- ance that in order to associate some of the attacks with the lluted water used in the preparation of the refreshments a the regatta day, it becomes necessary to admit a longer eriod of incubation than is usually met with in the case of teric fever. Still, twenty-seven cases were recognised ithin nineteen days of the date of the regatta, and though me appeared to be developed after an even longer interval, et it is quite possible that this may have been due rather to difficulty in determining the exact nature of the early ymptoms, than to the existence of a prolonged incubation- eriod. In enteric fever that period does somewhat vary, ut we think the cases in which it exceeds fourteen days orm quite the exception. Such instances, however, as Mr. osbrooke cites must be taken into consideration in deter- mining the question.

#### COMMUNICATION IN RAILWAY TRAINS.

MUCH has already been written regarding the causes of he recent sad fatality on the Midland Railway, but, looking to the future, importance is now attached chiefly to the best means which can be devised for the rapid stoppage of a train ravelling at a high rate of speed. While the evidence would indicate that Mr. Arthur, on account of previous nervous shock, was in the habit of taking some narcotic, and was at the time of the accident under the influence of such, it is clear that whether sufficient calmness and deter- mination to save the suspected victim was or was not shown at the first stoppage of the train, had the train been rapidly brought to a stand the chances of escape or of rescue would have been immensely increased. Besides the particular accident of fire there are many occurrences which may take place within a railway carriage demanding the immediate application of the brake, and even though the present absurd rule that a driver or guard must make himself sure of the necessity of stoppage before applying the power should be rescinded, any method which would place the command of the train in the hands of the passengers affected would be welcomed as a certain means of saving life, and of establish- ing confidence in the railway system where the method was adopted. By a peculiar coincidence such a method appears to have been successfully tried on the Caledonian Railway a few days after the Midland catastrophe. An escape-valve is placed on the Westinghouse brake, connexion attached to each carriage, a cord communicating with this valve is carried to each separate compartment, and placed within easy reach of the passenger. By pulling this handle the air escapes from the valve, and, even in spite of the driver, the train is brought to a stand very quickly, a loud whistling is maintained, and a disc appears to indicate the compart- ment where the action originated. Ample precaution is

taken that no malicious interference with the apparatus can take place without detection, and if such is attempted smart punishment may be inflicted. The recent trials under the direction of Mr. Drummond, the inventor of the method, were highly successful, a train travelling at thirty miles an hour being brought to a standstill in twenty seconds, even with the steam full on. If such results can be obtained we may hope soon to see the last of the cord system, and if rail- way directors do not willingly adopt some such method they may be coerced into doing so.

#### SIR STAFFORD NORTHCOTE AND MR. CHILDERS.

WE regret to learn that Sir Stafford Northcote and Mr. Childers have both broken down in health, and have been ordered abroad for change and complete rest, and we are not surprised at it. The work which devolved upon the former as leader of his party during the last session of Parlia- ment, the late hours which were the rule of the House, the very short interval of relaxation, and the renewed work and worry of an autumn session would be sufficient to use up the physical strength of even a younger man. Mr. Childers has had even a more trying ordeal to go through, having his office work in addition to his Parliamentary duties, and that office work, intensified by the serious responsibilities involved in the preparation for and carrying out of the Egyptian campaign, with the concomitant worry of questions in the House. It is only a matter of surprise to us that these two distinguished statesmen have been able to hold out so long, and we most sincerely hope that the rest now enforced upon them may prove successful in restoring them to us in renewed health and strength.

#### THE BOARDING-OUT SYSTEM v. PAUPER SCHOOLS.

WE are glad to find that a memorial, signed by a large number of members of Parliament, has been sent to the President of the Local Government Board, praying for an inquiry into the relative value of the two systems of pauper education—viz., that in schools and that in families. It is contended that vast schools are like barracks, where "pauper children" must, perforce of circumstances, be treated as a noun of multitude, with entire disregard to their individual needs and capabilities; and, as a necessary consequence, the best result is not obtained. This is a very important matter. There are doubtless great difficulties in the way of the board- ing-out system. It is hard to find suitable families, par- ticularly near cities and towns, and exceedingly perplexing to devise and work a sufficiently protective supervision. Nevertheless, the advantages of the family system are so superior to those of the school system that we earnestly hope it may before long be extensively adopted. The memorial now presented should greatly aid the progress of this most desirable reform.

#### MEDICAL DEPARTMENT, GENERAL POST OFFICE.

WE hear on trustworthy authority that the Postmaster-General contemplates a very grave departure as regards the Medical Department under his care. We are informed that one of the appointments rendered vacant in consequence of the death of Dr. Waller Lewis will not be filled by a medical man. The Postmaster-General has decided to give it to a lady. There are two medical appointments attached to the General Post Office, the one held by the late Dr. Waller Lewis, and the other at present held by Mr. George Steet in the Telegraph Branch. In this latter department the fair sex is especially represented amongst the employees; and it is for this reason, as we are informed, that, on Mr. Steet's elevation to the chief

medical officership, one of our fair rivals in the healing art is to take medical charge of the telegraph staff. We forbear to comment on the practical absurdity of directing a female medical inspector to inquire into and report upon the minutiae of every ailment which may temporarily incapacitate the rougher sex from a performance of their duties in the Telegraphic Department of Her Majesty's General Post-office. The Premier has, we understand, reserved to himself a power of supervision over the high appointments in the several departments of his government, and we hope it may not be too late for the exercise of his practical sagacity in this important matter.

#### DEATH OF PROFESSOR PIRRIE.

IT is our painful duty to record the death of Emeritus Professor Pirrie of Aberdeen, which took place at his residence in Union-street there, on Tuesday last. As is known to our readers, he had but recently resigned a connexion with the University of Aberdeen lasting over half a century. Professor Pirrie had a sharp attack of peri-hepatitis in April, from which he slowly recovered. By midsummer he was able to visit his patients. In the beginning of October an attack of acute inflammation of the prostate came on, ending in abscess. At first matters looked fairly well; but after two or three weeks the symptoms changed, the pus becoming fetid and symptoms of septicæmia developing. He then gradually sank. We hope in our next issue to give a sketch of the life and work of the deceased professor.

#### TENT HOSPITALS AT NEW YORK.

THE experiment which the New York State Board of Health is trying with tent hospitals is one which might be imitated upon this side of the Atlantic. These tents are divided into four compartments, and separated by a space of twenty feet. Upon one side is the sick-room, and upon the other the convalescent-room; a third compartment serves as a kitchen, still-room, and refectory, and the fourth as a disinfecting-room and a mortuary. Nothing which is calculated to increase the comfort of the patients has been lost sight of, and not an inch of ground has been wasted. Thus the sick-room is arranged to receive from six to nine persons; it is fourteen feet, and has 9420 cubic feet of air, but it can be increased in width without the least difficulty, so that each additional ten feet of room gives 2080 square feet, thus allowing of the admission of two or three additional patients. The beds are parted off by screens of thick muslin drawn tight upon a wooden frame.

#### SIR THOMAS WATSON, BART.

GRADUALLY increasing weakness is the only change to report in Sir Thomas Watson's condition during the past week. He still retains consciousness, and was much pleased to receive a kind message from a distant medical friend.

#### ROYAL COLLEGE OF PHYSICIANS.

THE Gulstonian Lectures for 1883 will be delivered by Dr. J. M. Duncan, the Croonian by Dr. J. E. Pollock, and the Lumleian by Dr. A. B. Garrod. These lectures will appear in THE LANCET, from the MSS. of the authors.

#### NAPPER TESTIMONIAL FUND.

A MEETING of the subscribers to this fund was held on Wednesday afternoon, J. Eric Erichsen, Esq., F.R.S., in the chair. It was resolved to close the fund; and a sub-committee was appointed, with full power to decide the form the testimonial should take, and to make arrangements for the presentation at an early date.

THE Health Ordinance recently passed by the City Council of Baltimore, Maryland, U.S.A., appears to excite great dissatisfaction amongst the medical profession in that city. The clause against which the loudest complaints are made is that which imposes upon the medical attendant the compulsory and gratuitous notification of a case of infectious disease he may be called to treat. The *Maryland Medical Journal* criticises the measure with considerable force, using pretty much the same arguments as those employed in England in opposition to the proposal.

AT the last meeting of the Metropolitan Asylums District Board, a report was presented by the General Purposes Committee upon the transfer of patients by ambulances from their homes to the infectious hospitals, and Sir E. H. Currie moved that the committees of the Deptford and Fulham hospitals be requested to submit plans and estimates for establishing ambulance stations at those hospitals. After some discussion the report was altered so as to include the whole of the hospitals where an ambulance station had not been provided, and was agreed to in its amended form.

HAYNES GIBBES ALLEYNE, M.D., L.R.C.S. Edin., one of the oldest medical practitioners in New South Wales, passed away on September 10th. He was President of the Medical Board, Sydney, member of the Board of Examiners of the University, and had in the course of his long and active life occupied various posts of medical distinction.

THE hospital at Cairo, which was formerly the dwelling-house of Arabi, and is now in full work under the auspices of Lady Strangford, has been favourably reported on to the Medical Board of Cairo by Dr. Grant Bey. The staff of nurses and other attendants, working under the direction of Dr. H. Sieveking, number over twenty.

THE Lord Lieutenant of Ireland has made the following appointments to his household:—Physicians in Ordinary: G. W. Hatchell and Thomas Nedley. Surgeons in Ordinary: Philip Crampton Smyly and Edward Dillon Mapother. Dentist: D. Corbett.

HER MAJESTY has signified her intention of conferring the honour of Knighthood on Mr. Oscar Clayton, F.R.C.S., Extra Surgeon in Ordinary to the Prince of Wales, and Surgeon in Ordinary to the Duke of Edinburgh.

## Pharmacology and Therapeutics.

#### PILOCARPINE AND CATARACT.

THE value of pilocarpine and jaborandi in the treatment of affections of the eye has been investigated by Dr. Landeberg. He states that in certain diseases they are useful, but he has met with some facts which suggest that their use may cause cataract. In four cases of detachment of the retina and one of serous choroiditis, in which the crystalline lens was perfectly transparent up to the commencement of the treatment, it afterwards rapidly became opaque. He also treated a horse for irido-choroiditis and large opacities of the vitreous, giving infusions of jaborandi leaves, and injecting pilocarpine beneath the skin. The morbid process was rapidly arrested, and the vitreous body became entirely transparent; but during the fourth week of treatment the crystalline lens was observed to become opaque. It is, of course, possible that the development of the cataract and the preceding treatment were simply coincident by chance, but the facts are at least suspicious.

## PILOCARPINE IN ATAXY.

The attacks of severe pain in ataxy frequently resist all ordinary sedatives. Dr. Oscar Jennings, of Paris, has recorded a case in which great relief followed the hypodermic injection of pilocarpine. Morphia had been used without effect, and an energetic employment of the thermo-cautery was also useless. An emetic produced temporary relief, but the pain returned next day, with constipation, vomiting, and retention of urine. Ether spray, bags of warm water, and sinapisms to the spine and abdominal walls gave only transient relief; but an injection of pilocarpine cut short the attack at once as soon as the diaphoresis was established, and no further attack occurred.

## CAFFEINE IN HEART DISEASE.

Caffeine has been largely employed as a diuretic, but it has been little used for its action on the heart. Lépine asserts that it is capable of producing the same effects as digitalis, over which, in some cases, it has decided advantages. It is, however, necessary to employ it in large doses, from sixty centigrammes to two grammes per day. The effect is more rapid than that of digitalis; in less than twenty-four hours the pulse will fall from 160 to 100 or 80 per minute; and the force of the heart's contractions is increased in just the same way as with digitalis. Caffeine is, however, better borne, and seems to be eliminated more rapidly than digitalis. Among its inconveniences, however, are the occasional production of insomnia, and a nervous condition which renders it necessary to suspend it. M. Lépine has never given it for more than ten days. Another objection is its very high price. A Paris physician, M. Huchard, has also praised it highly in the same cases, and in similar doses, especially for its diuretic effect. Coffee is, it may be noted, an old remedy. Zwinger recommended it in 1725 for dropsy, and Honoré in 1846 for albuminuria.

## ADONIS VERNALIS.

The Adonis vernalis has been used in some forms of heart disease, and its constituents have been recently studied by Dr. Cervello, who has obtained from it only one active substance, a glucoside, which he has named "adonidin." Only a small quantity was obtained from two kilogrammes of the plant. The substance is extremely energetic, and seems to be contained in small proportion. It is non-nitrogenous, colourless, odourless, amorphous, and extremely bitter, soluble in alcohol, but only slightly soluble in ether and water. It is precipitated by tannic acid, the precipitate redissolving in much water. It is insoluble in cold dilute hydrochloric acid, but on being heated it splits up into sugar and a substance insoluble in ether. Adonis vernalis is said to have an action similar to digitalis, but not to be cumulative in its action, so that it can be safely given for a considerable time without danger. The action of adonidin seems to be identical with that of digitalin. Cervello's researches have been published in the *Archiv f. Exp. Path. u. Pharmacologic*.

## NAPHTHALIN IN SCABIES.

Naphthalin was first employed in scabies by Kaposi, its value being suggested by the use which furriers make of it as an insecticide. It has been further used in the treatment of sixty cases of this disease by Fürbringer, who reports that it is most successful. It is employed in a 10 or 20 per cent. solution in oil. In one case it caused a slight and very transient albuminuria. Although the parasitic affection was quickly cured, naphthalin seems to have no influence on the secondary eruptions, which, in some cases of irritable skin seem to be augmented by it. In other skin diseases, especially those in which large surfaces are exposed, naphthalin is to be avoided. Fürbringer treated a case of psoriasis with a daily application of five to ten grammes of the above solution without benefit to the skin eruption, and with the result of causing a nephritic albuminuria. Neither in chronic eczema, nor in tinea tonsurans, did it do good.

## WARM WATER IN JAUNDICE.

Möller has employed with success the injection of a large quantity of warm water into the large intestine in catarrhal jaundice. The experiments of Röhrig have shown that such injections have the effect of increasing, for a considerable time, the secretion of bile; and Peiper showed that the bile was thus rendered more diffuent. While the amount of water in the bile was increased, that of solid matter was lessened. About six hours after the injection, the solids rise above the normal, and the water falls below it.

## PLANTAIN AS A STYPTIC.

An old styptic, mentioned by Shakespeare and recommended by various writers, from Pliny to Culpepper, plantain has been almost entirely overlooked by modern writers on therapeutics. Professor Quinlan, of Dublin, found it in use as a popular remedy in a remote district in Ireland, and has tried it extensively with the best results in cases of external hæmorrhage suited to the use of styptics. In cases of internal bleeding from the lungs, the kidneys, the bowels, and in menorrhagia he has got fair results from large and repeated doses of the juice, either fresh or fortified with alcohol or glycerine. At the recent meeting of the British Pharmaceutical Conference, at which these results were mentioned, he exhibited a number of specimens—(1) dried leaves, (2) a mixture of powdered leaves and glycerine, (3) the juice with sufficient alcohol to prevent it from spoiling, (4) the juice mixed with glycerine, and (5) a green extract. With the last he has not yet obtained satisfactory results. The powdered leaves alone, or mixed with glycerine, may be employed, the latter being intended to imitate the popular preparation, which is made by chewing the leaves. Chemically it does not contain tannin, and is compatible with salts of iron, alkaloids, other metallic salts, and preparations of ergot. Observations on the vessels in the tail of gold fish show that the application does not influence the circulation in the larger vessels, but great retardation occurs in the capillaries.

## SALTS OF MANGANESE.

The action of certain little-studied salts of manganese, that compound with molybdenic and tungstic acids, has been investigated by Merti and Luchsinger (*Centralblatt für die Med. Wissenschaften*, No. 38). The same symptoms were produced in various animals experimented on. In all a depression of all the functions of the nervous system was produced. Somnolence was succeeded by diminution in reflex action, lessened respiratory movements, and lowered blood pressure. As the paralysis increases the heart beats with increasing frequency and force. With these phenomena there is a gradual fall in temperature and in the production of heat. In warm-blooded animals there is also considerable irritation of the intestinal tract, apparently connected with the elimination of the salts. Diarrhoea even follows their hypodermic injection, and vomiting occurs early in those animals which are disposed to it; and when the poisons are injected under the skin, even the first vomit shows traces of their presence.

## Public Health and Poor Law.

## LOCAL GOVERNMENT DEPARTMENT.

## \* REPORTS OF MEDICAL OFFICERS OF HEALTH.

*Port of London.*—According to the annual report of Dr. Collingridge, medical officer of health for the Port of London, the inspection of shipping is maintained with considerable stringency. It is, however, urged that in order to effectually protect the metropolis from the importation of infectious disease by the Thames route, there should be means of detaining vessels at the entrance of the port until any patients affected have been removed to hospital. Special arrangements do already exist as to this, with respect to cholera, plague, and yellow fever; but they are also needed as regards other infectious diseases, and the port authority is in communication with the Board of Trade with a view of securing an alteration of the law in this respect. At present when ordinary infectious diseases are found to prevail on a ship, no power of detention exists, the vessel is allowed to pass up the river, and the cases are only removed after arrival in dock. Quarantine, as such, no longer exists in this country; it is replaced by a system of medical inspection and of isolation, and, according to Dr. Collingridge, the quarantine laws need no longer be retained in the statute book were it not for the public disadvantage at which this country would be placed in its dealings with other nations in case we had nothing which we could call quarantine. The action taken by the port authority in connexion with the polluted state of the Thames is fully entered into, and it is pointed out that whilst minor sources of sewage pollution

are every year being dealt with, the liquid filth being diverted from the river, the principal source of pollution derived from the great metropolitan outfalls continues steadily to increase. The port authority has for a long time been taking active steps to free the river from this sewage pollution, and to its activity we have, doubtless, in the main to attribute the appointment of the Royal Commission now sitting on the subject. Scurvy, it is curious to learn, is steadily on the increase amongst seamen, and this is attributed to the fact that owners have come to place so much reliance upon the antiscorbutic effects of lime-juice as to have sanctioned the exclusion of several important and essential articles of food from the diet of their sailors. Dealing with the question of emigration, Dr. Collingridge refers to the enormous flow of people who early in the year passed through London on their way to America, and to the absolute necessity for some proper arrangements for their medical inspection on arrival in the port. This subject is, amongst others relating to the health aspect of emigration, now under investigation by Dr. Blaxall, R.N., one of the medical inspectors of the Local Government Board.

*York (Urban).*—The medical officer of health for the City of York (Mr. S. W. North), has issued a report upon the health and sanitary condition of this urban sanitary district during the third or summer quarter of this year, which deserves the serious attention of its sanitary authority. The estimated population of this city in the middle of this year was 50,127. The birth-rate last quarter was somewhat below the average, while the death-rate was high, and equal to 22.6 per 1000, exceeding by 3.7, or nearly a fifth, the mean rate in the "fifty other large town districts" dealt with in the Registrar General's quarterly return. The zymotic death-rate in York was equal to 6.9 per 1000, against 3.6 in the fifty towns before mentioned; this high rate of zymotic fatality was mainly due to the very high mortality from diarrhoea, which caused 61 deaths during the three months, against 130 and 32 in the corresponding periods of 1880 and 1881. Summer diarrhoea appears to be exceptionally fatal in York, and is the cause of terribly high rates of infant mortality. The report before us shows that in the quarter under notice the proportion of infant mortality, measured by the proportion of deaths under one year to births, was equal to 266 per 1000, whereas the mean rate in the Registrar General's fifty town districts did not exceed 167. Mr. North distinctly points out the various forms of filth accumulation and consequent contamination which are the constant source of ill-health and low sanitary condition, and pertinently remarks that "children are peculiarly susceptible to the evil influence of foul and polluted air." He calls particular attention to foul privies and ashpits, in close proximity to dwelling-houses, through which the contents of such ashpits have to be taken when emptied, to ill-constructed house-drains and unventilated sewers as among the most fertile sources of filth contamination, and adds, "I regret that most, if not all, these causes exist over the greater part of the city." Mention is made of an outbreak of typhoid fever resulting in fifteen or sixteen cases, which is a serious warning in a city, the sanitary condition of which is not more satisfactory than that of York appears to be. The growth of the city and the sanitary welfare both of the city and its suburbs seem to demand the extension of the boundaries of the city in order to place the whole under one sanitary authority. The medical officer of health fully endorses the desirability of the proposal, and says, "I know no argument, sanitary, social, or economic, to the contrary." In the meantime, however, the York Town Council has its hands full in order to redeem their present responsibilities as regards the health of the city.

*Madeley.*—Dr. Thursfield reports an outbreak of diphtheria at Trounbridge, in the Madeley urban district. So far as he could learn only seven houses had been affected, but the attacks were attended by an exceptional fatality, five cases having been fatal. The cause of the disease remains unexplained, but Dr. Thursfield considers the history of the outbreak as supporting the view that dampness of site has a distinct influence, if not on the causation, at least on the spread and severity of diphtheria. The houses affected were principally dwellings so built into the sides of sloping hills that they were necessarily wet, and the existence of other houses higher up made it unsafe to remove the earth with a view of securing a dry area in each case. Similar conditions have before been observed in connexion with diphtheria in Wales and other hilly and mountainous districts.

*Lincoln.*—Dr. Harrison has issued his report on the recent outbreak of small-pox in the city of Lincoln. The first case occurred in April, and the patient was removed to the workhouse. The hospital belonging to the city was opened on May 6th, but it had almost at once to be enlarged so as to accommodate sixteen patients, and it continued, together with the workhouse hospital, to receive patients up to August 30th. In all, fifty patients were thus isolated, and twenty-one cases were treated elsewhere than in hospital. The result in some respects is highly satisfactory; thus, out of twenty-eight vaccinated persons treated in the city hospital not one died; whereas the death-rate among the unvaccinated reached 50 per cent. In other respects the history of the case cannot be regarded with the same satisfaction. Thus, in the first place, the disease lasted some four months before it could be eradicated; and, secondly, Lincoln has had to make hospital provision in an emergency; and when hospital buildings are erected under such circumstances, they rarely, as has been so convincingly proved in the official report on the "Use and Influence of Hospitals for Infectious Disease," answer the permanent requirements of the district. People suffering from small-pox can, it is true, be got into such buildings; but small-pox is not the infectious disease mostly needing isolation in this country; and where buildings are erected under the influence of panic, they, with but few exceptions, suffice for the proper isolation of scarlet or enteric fever. This, perhaps, is already recognised at Lincoln, for we read in the report, not that the building is to be maintained in readiness for the immediate reception of any cases of infectious disease which may arise in the city, but that when the small-pox had subsided "the hospital was closed."

*Belfast.*—During the four weeks ending the 21st ult., the births registered amounted to 536, and the deaths to 401, or at the rate of 25 per 1000. Of these latter 108 were due to lung disease, and two cases of small-pox proved fatal. The mortality from measles, scarlet fever, and diarrhoea was above the average, but the deaths from fever were very few. A fresh outbreak of small-pox took place, but those attacked were removed to the hospital for contagious diseases, and the usual precautions taken to prevent the disease spreading.

## VITAL STATISTICS.

### HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5607 births and 3668 deaths were registered during the week ending the 18th inst. The annual death-rate in these towns, which had been equal to 21.3 and 21.7 per 1000 in the two preceding weeks, further rose last week to 22.6. The lowest death-rates in these towns last week were 13.9 in Birkenhead, 16.6 in Bristol, and 17.8 in Leicester. The rates in the other towns ranged upwards to 28.0 in Liverpool, 28.6 in Halifax, 29.9 in Manchester and Preston, and 30.7 in Sunderland. The deaths referred to the principal zymotic diseases in the twenty-eight towns were 510, showing an increase of 42 upon the number in the previous week; 140 resulted from scarlet fever, 115 from measles, 82 from "fever" (principally enteric), 69 from diarrhoea, 65 from whooping-cough, 30 from diphtheria, and 9 from small-pox. The lowest death-rates from these zymotic diseases occurred in Derby, Bradford, and Huddersfield, and the highest in Newcastle-upon-Tyne and Sunderland. Scarlet fever caused the highest death-rates in Birmingham, Sheffield, Newcastle-upon-Tyne, and Liverpool; measles in Hull, Cardiff, and Sunderland; whooping-cough in Plymouth and Preston; and "fever" in Hull, Brighton, and Sunderland. No fewer than 21 of the 31 deaths from diphtheria in the twenty-eight towns occurred in London. Small-pox caused 4 deaths in London, and 5 in Newcastle-upon-Tyne. The number of small-pox patients in the metropolitan asylum hospitals, which had been 70 on each of the two preceding Saturdays, was 73 at the end of last week; 16 new cases of small-pox were admitted to these hospitals during the week, against 7 and 12 in the two previous weeks. The deaths referred to diseases of the respiratory organs in London, which had been 347 and 330 in the two preceding weeks, rose again to 345 last week, but were 111 below the corrected weekly average. The causes of 98, or 2.7 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Norwich,

Leicester, and Bolton. The proportions of uncertified deaths were largest in Salford, Blackburn, Halifax, and Hull.

#### HEALTH OF SCOTCH TOWNS.

The annual death-rate in the eight Scotch towns, which had been equal to 24.3 and 22.0 per 1000 in the two preceding weeks, rose to 25.8 in the week ending the 18th inst.; this rate exceeded by 3.2 that which prevailed last week in the twenty-eight English towns. The deaths referred to the principal zymotic diseases in these Scotch towns, which had been 85 and 89 in the two previous weeks, further rose to 98 last week, and were equal to an annual rate of 4.2 per 1000, and 1.1 above the rate from the same diseases in the English towns. The fatal cases of whooping-cough were 26, and showed a marked increase upon recent weekly numbers, no fewer than 19 being recorded in Glasgow. The 24 deaths referred to diphtheria corresponded with the number in the previous week, and included 9 in Glasgow, 5 in Leith, and 3 each in Edinburgh, Dundee, and Greenock. The deaths from scarlet fever, which had been 13 and 5 in the two previous weeks, rose to 16 last week, of which 7 occurred in Glasgow, 4 in Edinburgh, 3 in Paisley, and 2 in Leith. Diarrhoea fatality showed a further decline from that recorded in recent weeks. The 8 deaths referred to "fever," included 2 in Glasgow, 2 in Dundee, and 2 in Perth. Three of the 7 fatal cases of measles occurred in Glasgow and 2 in Dundee. The deaths referred to acute diseases of the lungs in the eight towns, which had been 135 and 130 in the two preceding weeks, rose to 172 last week, and exceeded by 50 the number in the corresponding week of last year. The causes of 117, or 19 per cent., of the deaths registered in the eight towns last week were not certified.

#### HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 20.4 and 27.7 per 1000 in the two preceding weeks, was equal to 26.1 in the week ending the 18th inst. During the first seven weeks of the current quarter the death-rate in the city averaged 23.4 per 1000, against 20.0 in London and 18.7 in Edinburgh. The 174 deaths in Dublin last week showed a decline of 11 from the number returned in the previous week. The deaths from the principal zymotic diseases, which had been 14 in each of the two previous weeks, declined to 11 last week, including 3 from "fever," 3 from whooping-cough, 3 from diarrhoea, and 2 from diphtheria. The death-rate from these zymotic diseases was equal to 1.6 per 1000, while the rate from the same diseases last week was 3.3 in London and 2.7 in Edinburgh. The deaths referred to "fever," which had been 5, 7, and 8 in the three preceding weeks, declined to 3 last week. The 3 fatal cases of whooping-cough, however, showed an increase, and the 2 deaths from diphtheria exceeded the number in any week since the end of September. The deaths of infants showed a decline, whereas those of elderly persons were more numerous than in any week since the end of March last.

"Audi alteram partem."

#### "THE DISCOVERY OF TRICHINA SPIRALIS."

To the Editor of THE LANCET.

SIR,—Professor Owen is decidedly in error; but doubtless he is just as unconsciously so as he is guiltless of any wish to deprive his eminent friend, Sir James Paget, of the credit which legitimately associates itself with the fact of the discovery of *Trichina spiralis*. Professor Owen was not the discoverer of this parasite. In the pages of THE LANCET and in the columns of *The Times* for 1866 this question of priority was exhaustively discussed—Sir James Paget himself, Dr. Wilks, and several other members of the staff of Guy's and St. Bartholomew's respectively taking part in the discussion. If Professor Owen will peruse Sir James Paget's most instructive letter (THE LANCET, March 10th, 1866,

p. 269), he will see that the "find" was made on February 2nd, 1835, and that the Bartholomew's student then "ascertained that nearly every cyst contained a small worm coiled up." What follows in that letter is even more to the point. "I was invited," says Sir James Paget, "as the discoverer of the entozoon, to communicate the facts respecting it to the Abernethian Society, and I did so on February 6th, the chair being occupied by Dr. Arthur Farre." If this statement be not a sufficient justification of my record in Dr. Quain's Dictionary, I invite Professor Owen further to read the "extract" quoted in the letter (published in THE LANCET of the same date) by "two former Presidents of the Abernethian Society." That important document closes with the significant remark that "the discovery and description of the trichina were communicated to the Abernethian Society eighteen days before Professor Owen's paper was read at the Zoological Society."

Here the matter might well rest but that the claims of others as to priority demand a passing word. I refer more especially to those of Hilton; for as to the merits of Klencke (1829), of Peacock (1828), and of Tiedemann (1821), it would be a waste of time to reconsider them. Speaking generally, the Germans have not treated this question with their usual acumen. By far the best accounts of the history of the discovery of trichina are those of Leuckart and Pagenstecher; that of the latter *savant* being the more complete of the two. Professor Pagenstecher declares for Hilton. He admits that "Hilton first saw the capsules, but not the trichinae," and yet with some inconsistency, I think, previously and emphatically exclaims: "Es darf also wohl unbedingt Hilton als der Entdecker der Trichinen gelten" ("Die Trichinen," 1865, s. 7)! But Pagenstecher is right, if the standpoint of the trichina-capsule "find" (as determining the question of priority) is to be held of primary import. I dissent from that view, and I am glad to see that my efforts, made through the medium of various publications during the past eighteen years, have not been altogether fruitless. Thus, Assistant-Surgeon Glazier in his admirable Report published by order of the United States Congress, says: "Sir James Paget was the first to see the parasite coiled up in its capsule." In making that statement, however, Mr. Glazier very properly acknowledges the prior claims of Hilton and of Peacock in reference to the discovery of the "specks" which are now universally admitted to have been calcified trichina-capsules.

I regret that Professor Owen should have thought it necessary to re-open this question, which I have elsewhere treated of and at much greater length than it was possible for me to do in Dr. Quain's Dictionary. Permit me to add that I shall esteem myself fortunate, indeed, if the fifty other brief articles contributed by me to that comprehensive work shall be found to stand the test of criticism equally well with that one upon which Professor Owen has been pleased to bestow some comment.

I am, Sir, yours truly,

London, Nov. 19th, 1882. T. SPENCER COBBOLD, M.D.

#### "THE CONTAGIOUS DISEASES ACTS."

To the Editor of THE LANCET.

SIR,—My experience with regard to the moral effect of the above Act during the six years that I assisted in its administration at Woolwich, is quite at variance with that of Dr. Truman of Nottingham, as published in your issue of last week. During the earlier months of its operation it was the custom for most of the women to present themselves for examination in a filthy, disorderly, and most shameless condition of mind and body; but after repeated and gentle appeals to their better natures all this was soon greatly ameliorated and the duties of my office were, in consequence, performed with much less violence to my own feelings and to theirs. I know, also, of many instances in which the young wives of soldiers, who had married without the consent of their colonels and were consequently often left behind in a destitute state whenever their husbands were ordered away to a distance inaccessible to them, have been rescued from an immoral life solely through the interposition of the Act in question. In the face of such facts, I trust that the profession will accept the observations of Dr.

Truman with reserve, and not allow the practical aspect of the question to be obscured by the moral one.

I am, Sir, yours faithfully,

J. BERESFORD RYLEY, M.D.

Finsbury-square, November 21st, 1882.

To the Editor of THE LANCET.

SIR,—In your valuable journal of Nov. 11th, I was much pleased with the report of the "First Five Years' Work at the Liverpool Seamen's Dispensary for Venereal Disease," and venture to suggest a few remarks for the benefit of our mercantile sailors, many of whom go to sea suffering from either gonorrhœa, chancre, or syphilis.

It seems a pity that sailors of the mercantile marine cannot be placed under a Contagious Disease Act, and prevented from signing articles when suffering from any one of the three diseases mentioned above; and it is surprising that the Board of Trade, or the directors of large companies, or the owners or captains of vessels have not taken the matter up, and compelled every man before signing articles to be examined.

As an old ship-surgeon, I can confidently say that I do not believe there is one of our ships leaves England for a foreign port without there are five or six of the crew suffering from the disease; and when surgeon on board one of the steamers of one of the largest companies leaving England, I had three saloon stewards suffering from bubo and chancre under my care; but they were not allowed to be on the sick list, as they "could not be spared."

I feel certain that there are many ship-surgeons who will support my statements; and I can only suggest that the Board of Trade ought to make it a standing rule for the crew of every ship before signing articles to be examined by a medical man.

I am, Sir, yours faithfully,

London, Nov. 1882.

EDWARD A. BURGESS.

## ON HOLIDAY-MAKING.

To the Editor of THE LANCET.

SIR,—All occupations, however varied they may be, require to be alternated fairly with rest and recreation. It is a great mistake to suppose that most and best work can be done when these aids are omitted. No occupation that calls forth special mental and physical work should fill more than one-third of the daily life. In our profession, with its constant cares, this is impossible, unless we can get quite away from our field of action, and even then many of us are so accustomed to constant application that we could not enjoy a holiday of idleness. It may be said without fear of contradiction that no work is more exhausting than that of medical men, and none more imperatively needs to be interrupted. I am pleased to say that my patients were unanimous in hoping I should be able to get away as well as themselves. In return for this consideration I resolved to endeavour so to employ my holiday that it might prove beneficial to all parties. I first visited Aix-la-Chapelle, or Aachen, with its neighbourhood Burtscheid, almost identical in their waters except in their heat. This is the chief sulphur bath of Germany. I stayed at the Grand Monarch Hotel. The proprietor, Mr. Dremel, is also the proprietor of the Emperor Bath Establishment. On learning that I was travelling in order to gain a practical knowledge of the waters and baths, he generously put his private carriage at my disposal while I remained, and with his servant as guide (after seeing all there was to be seen from a medical point of view) I "did" Aix and its neighbourhood most satisfactorily and cheaply. It is not my intention to give now a description of the baths I visited, or of the character of the mineral waters, but simply to state what I did comfortably in a three weeks' holiday. At each place I followed the old Bath rules—

"Arise betimes; to pump repair—  
First take the water, then the air;  
Most moderate be in meat and drink,  
And rarely, very rarely, think!"

From Aix I went to Homburg, justly called the queen of continental spas. Here, in addition to the usual routine, I had a mud bath, a poultice all over. From Homburg to Wiesbaden, with its numerous baths—most of the large hotels have a regular suite of baths, so that it is unnecessary to leave your hotel. I stayed at the Rose Hotel, well

situated, close to the drinking springs. Here I enjoyed an electric bath. From Wiesbaden to Kreuznach, where I saw a new house, lately erected, called the Inhalatorium. The salt water is constantly trickling down all round the house, the sides of which are constructed of open woodwork of thorn branches. The air is certainly saturated with the salines, but it gives one the impression of being as likely to cause as to cure disease. At Kreuznach, on the way to the salt works, I visited the Victoria Convalescent Hospital for children. The building is well constructed on sanitary principles. At Mucster Am Stein I witnessed the process of making common salt from spring water. From Kreuznach I again crossed the Rhine to Ems, the pearl of baths. It was a treat to get into clear water once more, the unstained marble and pale green water recalling to mind some pleasant bathing not so far from home. After visiting my friend, Professor Trendelenberg, at Bonn, and seeing his hospitals (feeling refreshed, but not invigorated, by the amount of washing both outside and inside which I had undergone of late), I passed from Brussels, Antwerp, Rotterdam, Amsterdam, the Hague, to Scheveningen, the gay and fashionable Dutch watering-place, the clear and bracing air of which gave the finishing touch to a most pleasant and profitable outing.

My object in writing this sketch is to make the following facts more generally known: that at these German health resorts, while there is a tax on all visitors who remain over five days, medical men, and in most places their families, are exempt, and free to the gardens, the baths, the concerts, the use of the reading-rooms, and all those luxuries which tend to make life at these resorts so extremely enjoyable. The resident physicians are most anxious to assist in every way, by giving all the information in their power, explaining the various kinds of baths, the inhalation apparatus, condensed air chambers, &c. When visiting these English colonies it is advisable to take a plentiful supply of visiting-cards—let them only tell your profession,—otherwise you may be harassed with questions, or to pass your opinion on the various dishes, the action and qualities of the wines, the diet and treatment prescribed by the physicians, and so on.

I conclude this hasty sketch with many thanks for the kindness and attention received from my professional brethren, the proprietors of the baths, and the officials generally; and with the hope that the few hints thrown out may assist some of my fellow workers in deciding how to plan their own holidays, while not losing sight of the interests of their patients. In the words of one often quoted by balneologists: "The knowledge of such baths is especially worthy of the physician, for in it are comprehended not only the whole of medicine, but also the principles of all the natural sciences with which a physician should be acquainted."

I am, Sir, yours obediently,

W. SINCLAIR THOMSON M.D.

Ladbroke-grove, W., Oct. 1882.

## "SCURVY."

To the Editor of THE LANCET.

SIR,—The veteran Professor of Hygiene in Paris, Bouchardat, has the following at page 329 of his *Annuaire* for 1881: (I give an exact translation.) "Salted meats differ from fresh not only because they are saturated with sodium chlorides, but also because this last has substituted itself in the place of the chloride &c. of potassium, more soluble than it (the sodium), which is eliminated and is found in the brine, as also the creatine and the creatinine, and certain other saline principles of meat." The presence or absence of lactic acid salts (which, like citrates, tartrates, &c., all form carbonates in the body, so that the acidity is only temporary) he does not seem to consider of much importance, but thinks Dr. Garrod's doctrine is well-nigh proved. At page 330 of the *Annuaire* is the graphic sentence: "Le potassium est le métal des végétaux," so that it is no wonder that persons living on salted or even preserved (?) meats should benefit by anything containing largely a potassium salt—viz., fresh meat or fresh vegetables, fruit, wine, &c. But there was plenty of potassium in our mutton rations in the Crimea, and in bread and biscuit. I would at this stage draw attention to a fallacy, which seems to vitiate much of our Indian experience of scurvy. We set down as fresh vegetable eaters all the dried grain eating tribes, who

on active service often can get no fresh vegetables at all, and who actually, as I found on the Afghan frontier, often refuse a ration of dates, the antiscorbutic *par excellence* of the Arabian, Afghan, and all other desert tribes. The Abyssinians use honey in the same way. In India, amongst the grain eaters, as long as a certain amount of green vegetables (bajee) or fruit is procurable, and thus supplies potassium, &c., scurvy is unknown amongst many millions of vegetarians. It is only in the arid parts lying about Sind and the Punjab, &c., where green vegetables are so scarce, that it is ever seen. Certainly fresh vegetables contain enormous quantities of vegetable acids and potassium; but when we come to compare meat and grain, wheat, &c., we find that they have both about the same amount of mineral ash—viz., 1·6 per cent. One would conclude, therefore, that it is the very presence of lactic acid, as Parkes suggested, that makes meat a better diet than biscuits for scurvy. Does walrus meat develop excess of lactic, and retain it after cooking? If not, we must then suppose that it was the ration of preserved vegetables which helped the crew of the *Eira* (for, whether the muscle of meat, as Dr. Ralfe points out, be alkaline at first and acid afterwards through lactic acid, Parkes teaches that this acid simply goes to form alkaline carbonates in the body.) Besides, it has never been proved that the blood is acid in scurvy; in fact it never is. But it has been proved that a timely administration of almost any vegetable acid, almost citric, malic (lactic?), in combination with potash, is a perfect prophylactic against scurvy. Let not the Admiralty forget this, nor the labours of Lind, Van Swieten, &c.

I am, Sir, yours truly,

CAMERON MACDOWALL,  
Brigade Surgeon, Bombay Army.

Deesa, Sept. 4th, 1882.

To the Editor of THE LANCET.

SIR,—In a foot-note to page 496 of his "Manual of Practical Hygiene," fifth edition, (London, Churchill, 1878), Parkes says:—"For a good deal of evidence up to 1848, I beg to refer to a review I contributed on scurvy in the *British and Foreign Medico-Chirurgical Review* in that year. The evidence since this period has added, I believe, little to our knowledge, except to show that the preservation and curative powers of fresh meat in large quantities, and especially raw meat (Kane's Arctic Expedition), will not only prevent, but will cure scurvy. Kane found the raw meat of the walrus a certain cure. For the most recent evidence and much valuable information, see the Report of the Admiralty Committee on the Scurvy which occurred in the Arctic Expedition of 1875-76 (Blue Book, 1877)." I think that the last sentence in the above is not Parkes' own, but that it must have been added by the editor in order to bring it up to the date of the issue of the current edition. The experience since then of the Arctic Expedition in the *Eira* coincides with these. I refer to that portion of the report where the author tells us that "our food consisted chiefly of bear and walrus meat, mixing some of the bear's blood with the soup when possible." And again: "I do not think that spirits or lime-juice is much use as an antiscorbutic, for if you live on the flesh of the country, even, I believe, without vegetables, you will run very little risk of scurvy. There was not a sign of scurvy amongst us, not even an anæmic face," (LANCET, Aug. 26th.) So that, as far as this question of fresh meat and raw meat and their prophylactic and curative properties are concerned, ample evidence will be found in other published literature to corroborate that of the *Eira*. But when you take up the question of the particular change which takes place in meat from its fresh to its stale condition, you will find a great deal of diversity and little harmony of opinion. Without taking up other authors on the subject, we stick to Parkes and compare his with Dr. Ralfe's views on this point. Parkes thought "fresh, and especially raw meat, is also useful, and this is conjectured to be from its amount of lactic acid; but this is uncertain," while on the other hand Dr. Ralfe repeats, as a probable explanation, too, of the reason of fresh meat being an antiscorbutic, that it is due to the absence of lactic acid. For, scorbutic, that it is due to the absence of lactic acid. For, from well-known chemical facts he deduces the following:—"In hot climates meat has to be eaten so freshly killed that no time is allowed for the development of the lactic acid; in arctic regions the freezing arrests its formation. The

muscle plasma, therefore, remains alkaline. In Europe the meat is invariably hung, lactic acid is developed freely, and the muscle plasma is consequently acid. If, therefore, scurvy is, as I have endeavoured to show ("Inquiry into the General Pathology of Scurvy"), due to diminished alkalinity of the blood, it can be easily understood that meat may be antiscorbutic when fresh killed, or frozen immediately after killing, but scorbutic when these alkaline salts have been converted into acid ones by lactic acid decomposition."<sup>2</sup> The view of the alkalinity of the blood coincides with Dr. Garrod's theory, which latter, however, appears to have as a *sine quâ non* the absence of a particular salt—namely, potash. I am inclined to think that, taking into account the nervous symptoms which are not infrequently associated with a certain proportion of scorbutic cases, resulting probably from the changes taking place in the blood, not unlike those which occur in gout and rheumatism, there must be some material change produced in the sympathetic system. In many of the individuals tainted with scurvy there were slight and severe attacks of passing jaundice in the cases which occurred in Afghanistan. Can we possibly trace this icteric condition to this cause? This is but a conjecture so far. But there certainly is in Garrod's observations an important point which, if applicable to all countries, climates, and conditions of life, is sufficiently weighty to indicate the necessity for farther research in that direction, and that point is this: the scorbutic condition disappeared on the patient being given a few grains of potash, though kept strictly on precisely the same diet which produced scurvy.—I am, Sir, yours truly,

Ahmedabad, India, 30th Sept., 1882.

JOHN C. LUCAS.

## DIAGNOSIS CASE.

To the Editor of THE LANCET.

SIR,—Having for some time wished to have various mechanical aids to diagnosis in a portable form and small compass, I instructed Messrs. Salt and Son of Birmingham, the surgical instrument manufacturers of this town, to make a diagnosis case. I am glad to say they have completed their task most ably and satisfactorily, and have produced a useful, light case containing nearly everything required for diagnostic purposes. The following is a list of the instruments, &c., included:—Sims' uterine speculum, Ferguson's nested specula, bivalve rectum speculum, nested ear specula, nasal speculum, Laycock's spatula ear syringe, urinometer and trial glass, three vulcanite cases, containing caustic

potash, nitric acid, and cupric test, hermetically sealed cyrtometer, spring measuring tape, stethoscope, ophthalmoscope, exploring trocar, Simpson's sound, male and female catheter combined, exploring sound, Thompson's sound and searcher, and clinical thermometer.

The case consists of two halves, and when close forms kind of reticule case; it is hinged, so that a receptacle left for the stowage of any addition the fancy of the individual practitioner may think desirable. The various instruments are securely fixed each in position; and the engraving gives a fair illustration of the case when closed.

<sup>1</sup> Op. cit., p. 498.

<sup>2</sup> THE LANCET, Sept. 2nd, p. 371.

I consider the case worthy of the reputation of the firm by whom it is manufactured.

Believing that many of my brethren would be glad to know of such a useful adjunct, I have thought proper to ask for a little of your valuable space for this notice.

I am, Sir, yours truly,

Birmingham, Nov. 1882.

WM. THOMAS.

### SCOTTISH NOTES.

(From our own Correspondent.)

PROFESSOR BAIN, of Aberdeen, delivered his address, as Lord Rector of that University, last week, and met such a reception from the students as is rare even under similar circumstances. The Professor and the other members of the University, who accompanied him to the platform, were received in such a disorderly manner, and the interruptions were so long continued, that the Lord Rector, the choice of the students themselves, was unable to continue his address, and ultimately handed it to the reporters. From such an eminent educationalist, and at a time when many changes are looked for in the near future of the Scottish universities, a more than ordinary treat was expected; but it will be generally allowed that the historical account of the rise and progress of these institutions was of less interest than would have been a full exposition of the views held by Dr. Bain regarding necessary changes. Certainly it is known that the Rector would give increased choice of avenue to the arts degree, and would favour a considerable introduction of science subjects; but this, which is perhaps the most pressing reform, received slight, though favourable, notice at his hands. With his concluding words, calling for a taste of the logic of freedom in the various curricula, most people will agree.

Opposition is springing up with regard to the proposed City Improvements Bill for Aberdeen, which it is not unlikely a large proportion of the profession will endorse. It appears that the effects of the Bill would be largely to increase the amenity of the city, and to give new means of communication with its various parts, while it is not so clearly shown that the number of rookeries, now the haunts of disease and death, to be demolished will be at all in proportion to the money spent. The large expenditure under the Bill would indefinitely postpone the demolition of such places as were recently condemned by the Medical Officer of Health.

In May last it was determined by the friends of the late Sir Wyville Thomson, Professor of Natural History at Edinburgh, that his distinguished services should be fully commemorated in his native town of Linlithgow. Proceedings were at once taken, and it now appears that a sufficient sum has been subscribed by friends from all parts of the world to allow of a bust for Edinburgh University, and a stained glass window in the old church of St. Michael at Linlithgow.

An unfortunate event has just occurred at the Institute for Imbeciles at Larbert. A nurse having the charge of two boys, having undressed them for the purpose of bathing, left them alone in the room for a short time. When she returned, she was horrified to find that, one of the children having gone into the empty bath, the other had unwittingly turned the hot water upon his companion, causing such extensive scalds that the child has since died. The whole matter is being investigated by the legal authorities. Whatever may be said as to the propriety of the change recently made in this establishment, in the substitution of a lay for a medical superintendent, it will be admitted that cases of this kind can only be adequately met by a resident attendant.

An epidemic of typhoid fever, showing much intensity and persistence, still exists in Brechin. Judging from the Sanitary Inspector's report as to the condition of the town, such an outbreak might well have been expected; and it is scarcely creditable that after the present lengthened experience of the fever such nuisances as are detailed should be allowed by the authorities.

The important and rapidly increasing town of Dumbarton finds it necessary to very largely extend its water supply. Complaints of scarcity have long been made in this town, but the matter seems now to be energetically taken in hand. Trarant is asking similar powers; and Wick has obtained an entirely new supply.

A special meeting of the Perth Water Commissioners has been held for the purpose of considering the reply of Mr. Trotter, L.R.C.P.Ed., to a recent communication of the town clerk, calling upon him to retract and apologise for statements made by him in a recent lecture. Mr. Trotter, in his reply, re-affirms that certain animals have been found in the water supply of the town both before and since his lecture; states that his sole desire is to impress upon the authorities the importance of removing the present wide-spread suspicion as to the purity of the water; points to the impossibility of detecting typhoid or other fever-germs by any known chemical test; and repeats his statement that until the sewage of the town ceases to be discharged in the immediate neighbourhood of the filter-bed each recurring epidemic will renew the suspicion regarding the purity of the water. He apologises for asserting that the authorities had carefully filtered the water before sending it for analysis, though he was informed that such was the case, and repeated the statement in good faith. After considerable discussion the Commissioners agreed to proceed no further in their threatened action for libel. It is believed that the recent withdrawal by the Brighton authorities of their proposed prosecution of THE LANCET had some effect in inducing the Commission to adopt this course.

It may be well to remind Scottish graduates who have changed their address since November last, or whose present address is not properly described in the Register, that Thursday the 30th inst. is the last day on which the Registrar can receive notice of such change for the present year. Gentlemen whose names are not found in the Register on November 30th properly described, will lose the right of voting for a member of Parliament should an election take place within a year from that date.

[In last week's Notes (second line), "magnificent" should have read *inaugural*.]

### IRELAND.

(From our own Correspondent.)

A CLUB for medical students in Dublin is in process of formation, and it is probable that in a short time the necessary arrangements will be completed for so desirable an undertaking. Mr. Barton, of the Adelaide Hospital, has, I understand, consented to act as president of the club.

The insanitary conditions under which the Crown witnesses exist while residing in Dublin were last week brought under the notice of the Drumcondra Town Commissioners by a report of their sanitary officers. In one of these houses, which contains five small rooms and a kitchen, twenty people were lodged; and in one room, eighteen feet by nine, there were found seven people, for whose accommodation there were but two beds. In another room six brothers and sisters slept together on two mattresses. The sanitary accommodation was of the scantiest, and it is surprising that the authorities allow such a state of things to exist. The commissioners have resolved to communicate with the Chief Secretary on the matter.

Last week the opening meeting of the University Biological Association for the session was held at Trinity College. The President of the Association, Mr. Bennett, delivered an address on the Physiology of Plastic Surgery. He referred more especially to the subject of restoration of noses, and exhibited a patient whom he had operated on four years previously. Dr. Macalister moved that the thanks of the Association be accorded to Mr. Bennett for his address, and, alluding to the subject of the discourse, said that the successful transplantation of tissue was an illustration of the independent life of tissue so removed. Every particle of organism which contained independent protoplasm was thereby independently alive, and, to adopt the grandiloquent language of modern science, man was a condition of aggregates of symbiosis.

The Board of Management of the Belfast Royal Hospital, on the recommendation of the medical staff, at the annual meeting held last week, have resolved to establish two new departments in that institution—viz., one for the treatment of diseases of women, and one for diseases of the eye and ear. There will be a dozen beds allotted for this purpose, but that class of disease will be mainly treated at the extern portion of the hospital. From the annual report it appears that the subscriptions last year amounted to

£1487, donations to £1346, and contributions from work-people and young men to £430. The Board notice with satisfaction that there was an increase in the annual subscriptions, and especially in the subscriptions of the working classes.

Dublin Hospital Sunday was held in the majority of churches in the Dublin district on the 12th inst., and as the day was an unusually fine one, the various places of worship were well attended; and it is to be hoped that the collections this year will exceed those of the preceding. St. Matthias' Church has had the high honour of being foremost in the ranks of contributing churches; and the incumbent, in the morning sermon, touched on the topic, and trusted it would not lose the high and honourable position it had obtained. The collectors, at the close of his address, included the Presidents of the Colleges of Physicians and Surgeons, Dr. J. Magee Finny, Dr. Robinson, and Mr. Croly; and a sum of £275 was obtained between the two services, or an advance of some £90 over that of last year.

Dr. Banks has been elected President of the Academy of Medicine in Ireland, and will hold office for three years.

## PARIS.

(From our own Correspondent.)

THE most contradictory reports have been in circulation concerning President Grévy's state of health, some of the newspapers going so far as to say that the malady he was suffering from was softening of the brain; and speculators have already been discussing as to who is to be his successor to the Presidency. But the following, which I obtained from M. Sée, himself the President's medical attendant, is the true statement of the case:—On this day week the President had a rather severe attack of indigestion after a copious and late dinner the night previous, when he had also freely partaken of some partridge, which was rather tainted. When M. Sée was sent for at noon, the President was in the second stage of indigestion, which M. Sée termed "dyspepsie intestinale;" this was accompanied by diarrhoea, nausea, and giddiness, and a sensation which the patient compared to that produced by seasickness. The next day M. Grévy was all right again, and he has since attended to his duties, and gone about without any further interruption, and has even since been out shooting.

It is in contemplation at the Institute to award to Monsieur J. B. Dumas a medal bearing his own effigy to commemorate the completion of his fiftieth year as member of the Institute, and for the eminent services rendered by the illustrious chemist to science and humanity.

A rather curious trial lately took place at Nîmes, in which the defendant, who was a doctor of medicine, was charged with having illegally practised his profession. This would seem rather paradoxical, and requires some explanation. The defendant, notwithstanding his professional position, consented to become assistant to a well-known charlatan at Vaucluse. The latter professed to have a secret remedy for the cure of cancer, and for other maladies pronounced incurable by the medical faculty. The doctor was kept in the dark as to the composition of the remedy, but he, nevertheless, prescribed, or rather signed the quack's prescriptions, for which he was sued before the Court and fined 200 francs. This, however, did not deter him from continuing his association with the quack, and he was again brought before the Court for having, at different times, extorted large sums of money from a lady who was, conjointly with his partner, under his treatment for cancer of the breast, which they promised to cure without operation within a short time. The lady, finding herself getting worse, abandoned the quack and applied for admission to the hospital, where the surgeon declared that operation was impossible owing to the destruction of the skin by the application of some strong caustic. The judge, in summing up, explained that although the defendant was a doctor of medicine, he nevertheless practised his art in an illegal manner, as he prescribed remedies the composition of which he was entirely ignorant or which was kept secret, whereas the possession of his diploma gives him the right to practise the art of cure, but only with such remedies that he can answer for. The Court therefore concluded that the defen-

dant was guilty of the illegal practice of medicine, but, as according to French law, this constitutes a simple misdemeanour and amenable to the police-court, he was fined only 15 francs, which, though small, the judge hoped would serve as a salutary lesson to him and future offenders.

Whatever may be said against the republican form of government, it cannot be denied that the French Republic has done, and is still doing, a great deal for the improvement of the condition of the working-classes, and particularly that of children and youths. For instance, a circular from the Minister of Public Instruction is being sent round to the different schools enjoining the masters not to overburden their young pupils with a multiplicity of subjects at the same time, as, far from such a practice being profitable to them, it would be rather prejudicial to their young minds, and would tend to disgust them with their studies. The circular also treats of the necessity of allowing the children more time for their meals than is now obtained, and more leisure for corporal exercises. The minister dwells upon the necessity of masters and teachers studying the constitution and natural aptitudes of their pupils, and of dividing the hours for study according to the average amount of intelligence of the boys of the same class, leaving them sufficient time for play and rest. And while the culture of the mind should be properly attended to, the physical development should not be neglected. Orders have been issued that gymnastics and athletic exercises should be introduced into every school and college.

The *Official Gazette* of last week contains decrees regulating the work of children and youths in the various manufactories. It is forbidden to employ children in the manufacture of salicylic acid, of celluloid, the various products of the nitrates and those of the chlorides of sulphur. Children under sixteen years and girls under eighteen are not to be employed as producers of motive force, connected with machinery of any kind. Boys and girls over twelve years may be allowed to draw any burden in the interior of manufactories and establishments on condition that the draught be performed on level ground, and that the load will not exceed 110 kilogrammes, including the vehicle. Boys only, from fourteen to sixteen, may be allowed to draw burdens on the public roads, on condition that they do not exceed 100 kilogrammes, vehicle included. It is forbidden to employ children in any manufactory where dust or other pulverulent substances are produced in the manufacture of articles from dry horn, bones, and from mother-of-pearl. A former decree regulated the hours for work for children and youths.

Paris, Nov. 21st, 1882.

## THE SERVICES.

BOMBAY MEDICAL ESTABLISHMENT.—Brigade Surgeon Lewis Stanhope Bruce, to be Deputy Surgeon-General. Surgeon-Major Cameron Joseph Francis McDowall, to be Brigade Surgeon.

BENGAL MEDICAL ESTABLISHMENT.—Surgeon-Major James Browne, M.D., to be Brigade Surgeon.

ADMIRALTY.—The following appointments have been made:—Deputy Inspector-General Francis W. Davis has been appointed to the Haslar Hospital, vice Wells; Staff Surgeon John N. Stone, to the *Duncan*, vice Thomson; Surgeon Malcolm V. Stace, to the *Duncan*, vice Hay.

## MEDICAL TRIALS.

### HIGH COURT OF JUSTICE, QUEEN'S BENCH DIVISION.—NOVEMBER 20TH.

BOOKER v. TAYLOR.

THIS was a case under the Public Health Act, sec. 124, with reference to the removal of a child having an infectious disorder to a hospital. The Act provides that if it shall appear on the certificate of a medical man that a child is labouring under such a disorder, and that the parents are in want of proper accommodation, a magistrate may make an order for the removal of the child to a hospital. In the present case, which arose at Coventry, there was such a certificate and such an order; but the mother of the child obstructed the removal, and was summoned for the offence.

At the hearing the magistrates entered into the validity of the order and declined to convict, and the question now arose whether they were justified in taking that course or ought to have convicted.

The court were clearly of opinion that the magistrates had no right to go behind the order, and enter into its validity, and were bound upon the evidence to convict if there had been an obstruction, and they sent the case back to the magistrates with that direction.

### MEDICAL NOTES IN PARLIAMENT.

In the House of Commons on Thursday, the 16th inst., on the motion of Mr. Gibson, a return was ordered of copy of the correspondence between Surgeon Wheeler and the Irish Government relating to Mr. Wheeler's attendance upon Mr. Shaen Carter.

On Friday, Mr. Trevelyan stated to Mr. Moore that the Irish Local Government Board had received no report, nor had they had any correspondence, with regard to the state of emigrants' lodging-houses in Londonderry.

#### *Inspection of Boarded-out Children.*

Mr. Dodson informed Lord George Hamilton and Mr. Bryce that it was no part of the duty of the Whitechapel Board of Guardians to provide means of periodical inspection of the homes of boarded-out pauper children, other than the usual inspection every six weeks by a member of the Boarding-out Committee. Beyond this, the homes were visited from time to time by an inspector of the Local Government Board. The Board adhered to its refusal to allow the Whitechapel Guardians to incur the expense involved in an additional system of inspection.

On Tuesday, Mr. Bryce moved for copy of the correspondence, which was presented; and Lord G. Hamilton gave notice that he will call attention to the subject early next session.

#### *An Irish Lunacy Question.*

On Monday, Mr. Trevelyan explained to Mr. Biggar the circumstances under which a lunatic named Robert Nelson was transferred from Belfast Asylum to the workhouse in 1879. It appeared that, his mania having assumed a harmless character, he was discharged from the asylum and admitted into the workhouse, and thereupon, by virtue of an existing practice, a dangerous lunatic was received from the workhouse into the asylum in exchange. Subsequently it transpired that there was a sum of money standing to Nelson's credit in the bank, and on the 14th of last month he was removed by his friends from the workhouse.

#### *Supervision of Nomads.*

On Tuesday, Mr. Dodson promised Mr. Burt to consider whether the law required amendment with the view of bringing temporary abodes, such as shows, tents, and vans, under the supervision of the sanitary authorities; and Mr. Mundella said he would consult with his right hon. friend as to the best means of securing the education of gipsy and other travelling children.

#### *The Norwich Vaccination Inquiry.*

On Wednesday, Mr. Hopwood gave notice of the following questions:—To ask the President of the Local Government Board, whether his attention has been drawn to the statement by the inspectors, in the inquiry into the case of eight children attacked with erysipematous disease after vaccination at Norwich, as to four of the cases which terminated fatally: "We cannot divest our minds of the strong impression that the lymph used in vaccinating those children must have carried with it the elements of the disease which they subsequently developed"; whether the public vaccinator had been recommended for award from the Parliamentary grant; whether Dr. Buchanan, the medical officer of the Local Government Board, in his memorandum charges the same vaccinator with using dirty or improperly cleansed instruments in the processes of vaccination during the years 1876 to 1880, and later; and whether it is any excuse by law, in answer to fresh summonses to vaccinate, for the parents of any of the children so attacked to urge their fear of similar risk to the survivors, if not, whether he proposes by legislation to relieve such parents from the compulsion at present existing.

#### *Sanitation in Dublin.*

Mr. Sexton asked whether, at a meeting of the Drumcondra Town Commissioners, a report was read from the sanitary officer of the board, stating that he had recently visited a house in Dublin which was occupied by Crown witnesses; that, in this house of five small rooms and a kitchen, he had found twenty people lodged; that one room, 18 ft. by 9 ft., was used as a sleeping apartment for seven persons—a father, three sons, and three daughters; the eldest daughter nineteen years of age, the eldest son fourteen—and only two beds for the whole family; that, in another room, six brothers and sisters, the eldest boy thirteen, the eldest girl eleven, slept together on two mattresses on the floor; that the earthen floor of the house was damp and dirty, and the bedding filthy; whether the sub-sanitary officer of the board was refused admission to another house in Dublin, also used for accommodation of Crown witnesses, and whether this house had been inspected by a medical gentleman, who reported that he found thirty persons lodged there; that he saw in front of the house "a mound composed of used-up palliasses, over which are thrown the products of an adjoining pigsty, and a garnishing of potato peelings and decomposing cabbage stalks;" and that there was a total want of sewerage and drainage, and a gross defect in sanitary accommodation; and what steps would be taken to punish those who were responsible for such a state of things.—Mr. Trevelyan said he was aware that a report was received from the sanitary officer to the effect stated in the question. Dr. Nedley also reported that in his opinion the sanitary state of the houses was not so bad as was alleged. Dr. Riggs was the medical officer for the district, and was medical attendant at the houses in question, and he said no reasonable complaint could be made against the houses. Dr. Nedley visited them, and found the inhabitants comfortably clothed, and looking contented. Admission was refused to the inspector because the constable in charge was directed not to admit anyone without an order.

On Thursday, in reply to Dr. Cameron, the Lord Advocate admitted that the diversity in the sanitary and police regulations of Scotch local Acts of Parliament was very unsatisfactory, and expressed his intention to bring in a general Police Bill next session. Mr. McLaren put a similar question in regard to English local Acts, to which Sir W. Harcourt replied that he thought the matter was covered by the standing order which was passed last August.

### Obituary.

#### PROFESSOR GEORGE GULLIVER, F.R.S., F.R.C.S.

THE profession will regret to hear that this distinguished anatomist and physiologist expired on Friday, the 17th inst., at his residence, the Old Dover-road, Canterbury, in the seventy-eighth year of his age. Born on the 4th of June, 1804, at Banbury, Oxon, he received his preliminary education under the Rev. William Woolston, B.A., of Addesbury, near Banbury, on the completion of which he was apprenticed to Messrs. Jones and Wise, surgeons in Banbury. Before the completion of his term he published his Catalogue of Plants in the neighbourhood. At the termination of his apprenticeship he came to London, and entered at St. Bartholomew's Hospital, where he soon became an especial favourite with teachers and pupils. Abernethy made him his Prosector of Anatomy and Curator of the Museum, and he was dresser to Mr. (afterwards Sir) William Lawrence. He was admitted a member of the Royal College of Surgeons on June 2nd, 1826, and in the following May was gazetted Hospital Assistant to the Forces. In 1843 he was present at the fatal duel between Lieutenant-Colonel Fawcett and Lieutenant Monro, and, with the others concerned, was tried at the Old Bailey for the murder, but acquitted.

When the new charter was granted to the College of Surgeons, Mr. Gulliver was one of the first elected, an event which gave rise to severe but reasonable remonstrances from senior medical officers in the Army to the Director-General of the Army Medical Department, Sir James McGrigor, who, sympathising with the memorialists, addressed the Secretary of State on the subject. An explanation was asked of the Council of the College, who very properly replied that such members of the College as Mantell, Owen, Newport, and

Gulliver had been chosen for the Fellowship in recognition purely of scientific merits, and that the Council would be apt to add others for the same reason as soon as their claims should become known to and recognised by the Council as valid; to this reply there was no rejoinder, and he matter dropped. Gulliver had previously been elected a Fellow of the Royal Society. In 1852 he was elected a member of the Council of the College of Surgeons, in the affairs of which institution he ever took the greatest interest, especially in the museum and library, serving on both committees. In 1861 he was elected Hunterian Professor of Comparative Anatomy and Physiology. During the tenure of this office he gave courses of lectures on his favourite subjects, Blood, Lymph, and Chyle of Vertebrates, in which were related the results of his extensive researches on these subjects. In his lectures an interesting proof was given that a moderate quantity of beer might promote the formation of a chief product of digestion, the chyle, and that this fact would have to be met by those zealous and benevolent persons who insist on the uniformly pernicious effects of fermented liquors. The character of the main morphological element of the chyle, which he had discovered and figured many years before, and named the molecular base, as now universally accepted by physiologists, afforded the means of detecting and estimating the quantity of chyle that escaped through an accidental opening of the human skin. In 1863 he delivered the Hunterian Oration, expounded points of Hunter's merits which had previously been ignored concerning the vital endowments of the coagulable lymph, the aggregation of the red corpuscles as the proximate cause of buffy blood, and the fact that the modern protoplasm was but a synonym of the coagulable lymph. This oration gave dire offence to the friends of a living celebrity, to whom he indirectly alluded for his anonymous attacks on his devoted friend Professor Quekett.

The opinion so often expressed in THE LANCET as to the election of examiners at the College of Surgeons was shared by Gulliver, who when told by a warm friend on the Council there was no chance of his being elected a member of the Court of Examiners, not being a hospital surgeon, contemplated resigning his seat, but ultimately decided on giving the Fellows an opportunity of expressing their feelings on the subject. This they did by, as Gulliver expressed it, "Confirming the offensive monopoly." On ceasing to be a member of the Council he busied himself in his literary pursuits, with occasionally short angling excursions; but frequent attacks of gout, increasing in severity, confined him to his house, and, latterly, for some time to his bed. Notwithstanding the constant and unremitting attention of his friend and medical attendant, Dr. Gogarty, Physician to the Kent and Canterbury Hospital, whose attentions at the last were shared by Dr. George Gulliver, Physician to St. Thomas's Hospital, son of the deceased, shortly before his death, in a letter to the writer of this notice, he observed: "For years I could only write in bed (as I am now writing), and have been unable to consult libraries, otherwise I would have attempted a history of Anatomy in England from the time of Hewson to that of Quekett. I have the main facts in my head, but could not be sure of giving them due accuracy and chronological sequence in the absence of books." Professor Gulliver leaves a widow and an only son, Dr. George Gulliver, M.A. Oxon., who, inheriting his father's love of natural history, went out as naturalist with the Venus expedition.

## Medical News.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—The following gentlemen, having passed the required examination for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 16th inst.:

Barnes, Walter Stanley, L.S.A., Cavendish-road.  
Cowen, Edward Ingepen, L.R.C.P. Lond., Dartford.  
Donald, James, L.S.A., Kingston-on-Thames.  
Dyson, Herbert Jekyl, College-street, Islington.  
Harris, Howard, L.R.C.P. Edin., Gullisborough.  
Hull, Walter, L.R.C.P. Lond., Swallow-place.  
Larder, Herbert, L.S.A., Wimbledon.  
Llewellyn, James Davies, L.S.A., Glyn Neath.  
Maynard, Edward Charles, Richmond.  
MacDonagh, William Frederick, Clapham-park-road.  
Morse, Herbert Ryding, L.S.A., Sutton.  
Peckett, A. W. Chalmers, L.S.A., Swansea.  
Potter, John Hope, L.R.C.P. Edin., Sheffield.

Rodley, John, L.R.C.P. Edin., Todmorden.  
Sharpin, Edward Colby, Bedford.  
Underwood, John Charles, L.S.A., Hemel Hempstead.  
Wigan, Charles Arthur, Portishead.  
Wothington, Sidney, L.S.A., Enfield.

Of the 96 candidates examined during last week, 51 passed to the satisfaction of the Court and obtained their diplomas; 14 passed in Surgery, and when qualified in the other subjects will be admitted Members; the remaining 31 failed to reach the required standard, and were referred. Twenty-three candidates who passed in Surgery at previous examinations, having subsequently obtained a qualification in Medicine and Midwifery recognised by the College, were also admitted Members.

The following gentlemen passed the first part of the Professional Examination for the Fellowship of the College at meetings of the Board of Examiners on Monday and Tuesday last:—

Charles Ernest Richmond and William Thorburn, Owens College;  
Thomas Horrocks Openshaw and David Thomas, London Hospital;  
Frederick Newland Pedley, A. E. Taylor, H. G. Dixon, Thos. Hugh Miller, Francis Heatherley, Jas. T. J. Morrison, John J. D. Vernon, and R. A. Baillie, Guy's Hospital; Charles E. H. Cotes and E. M. Little, St. George's Hospital; Walter Scott Thomson and Jas. Reid Roberts, Middlesex Hospital; Frank Tratman and William Connor Lysaght, Bristol; George Albert Hamerton, St. Thomas's Hospital and King's College; Herbert Watson Pilgrim, Edinburgh and King's College; John Elliott, Manchester and St. Bartholomew's Hospital; Edgar A. Hughes, Bristol and King's College; Archibald Keightley, St. Bartholomew's Hospital; Jean Samuel Kaeser, Strasbourg, Bale, and St. Thomas's Hospital; Arthur Wm. Dawson, King's College.

Of the 36 candidates examined on the above-mentioned days, 11 failed to satisfy the Board, and were referred for six months' further anatomical and physiological study.

**UNIVERSITY OF LONDON.**—The following candidates have passed the recent M.B. Examination:—

### FIRST DIVISION.

Adeney, Edwin Leonard, Guy's Hospital.  
Back, Herbert Hatfield, St. Bartholomew's Hospital.  
Batterham, John Williams, Westminster Hospital.

Pike, Charles James, University College.  
Robinson, Frederick, Leeds Infirmary and Medical School.  
Roedel, Waldemar Joseph, St. Bartholomew's Hospital.  
Scarth, Isaac, Owens College and London Hospital.  
Shove, Edith, London School of Medicine for Women.  
Watkins, Christopher James, University College.  
Woolby, James Ballie, King's College.

**COLLEGE OF PHYSICIANS IN IRELAND.**—At the November examinations the following obtained the Licences in Medicine and Midwifery of the College:—

**MEDICINE.**—James Tandy Bolger, John Clancy, Julia Cock, Robert Edmund Cooper, John Peter Garland, James Aloysius Morris, John Goodwin Shea.  
**MIDWIFERY.**—Jas. T. Bolger, John Clancy, Julia Cock, Robt. Edmund Cooper, Vicars Henry Fisher, John Peter Garland, Jas. A. Morris, John Goodwin Shea.

**APOTHECARIES' HALL.**—The following gentlemen passed the examination in the Science and Practice of Medicine, and received certificates to practise, on Nov. 16th:—

Bean, William Henry, Mersea, Colchester.  
Champ, John Howard, Chelmsford, Essex.  
Harrison, Charles, Braintree, Essex.  
Heathcote, Ralph George, Chatham-street, Manchester.  
White, Ernest Alfred, Grenville-street, Russell-square.

The following gentlemen also on the same day passed the Primary Professional Examination:—

John William Harris, Guy's Hospital; Richd. Park Griffin, St. Mary's Hospital; Walter Mitchell Hardy, Charing-cross Hospital; James Jesse William Stevens, St. Bartholomew's Hospital.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—In the list published last week of gentlemen who passed the First L.R.C.P. Lond., for George Jervis Rugg, read George Lewis Rugg.

THE late Jerome G. Kidder, Esq., of Boston, U.S.A., bequeathed \$50,000 to the Boston Lying-in Hospital, and \$25,000 to the Massachusetts General Hospital.

MR. THOMASSON, M.P. for Bolton, has promised £2500 towards the maintenance of the new infirmary of the town when the building is ready for the reception of patients.

DR. CHARLES EDWARD BARNARD, of Gulgong, has been appointed a magistrate of the colony of New South Wales.

VACCINATION GRANTS.—The following gentlemen have received the Government grant for efficient vaccination in their respective districts:—Dr. Newham of Winslow (seventh time); Dr. Alfred Hollis, Freshwater, Isle of Wight.

It has been decided by the Paddington vestry to advertise for tenders for the new infirmary for the parish. The building is to be erected on the workhouse grounds, and is to accommodate 250 patients.

At a meeting of the Sunderland Board of Guardians on the 16th inst. a recommendation of the Finance Committee was adopted that the salary of Dr. Ridley Dale, medical officer for Sunderland parish, be increased from £100 to £130.

DR. EDWARD EVANS, a young physician of Nicholasville, Kentucky, was shot dead by a lawyer in a dispute over a fee. The *New York Medical Record*, in which the event is reported, does not say whether the fee was the slayer's or that of the slain.

FLEET SURGEON ADAM, attached to the Royal Marine Artillery, Portsmouth, while on his way home on Monday night last, was attacked by two men. With the assistance of a gentleman who was passing at the time, Mr. Adam succeeded, however, in beating off his assailants. The outrage is supposed to have connexion with the fact of Mr. Adam having been a witness at a recent court martial.

VEEDY, JOHN, F.R.C.S. Eng., Professor of Ophthalmic Medicine and Surgery in University College, London.

ERSON, W. J., M.D. Durh., F.R.C.S. Eng., Medical Officer of the Folkestone Infirmary.

ESDELL, H., M.R.C.S. Eng., Surgeon to the Ashburton and Buckfastleigh Cottage Hospital.

AN BUREN, E. C. H., L.R.C.P. Edin., M.R.C.S. Eng., House-Surgeon to the Buckinghamshire General Infirmary, Aylesbury.

ERNEDE, F. E., M.D. Edin., M.R.C.S. Eng., Medical Officer of Health to the Borough and Port of Poole, Dorsetshire.

ALFORD, E., M.R.C.S. Lond., Medical Officer of Health of the Ramsgate Urban District, and Surgeon to the Ramsgate and St. Lawrence Royal Dispensary.

ALKER, A. DUNBAR, M.D. Edin., Medical Officer of the North Kensington and Kensal Town Provident Dispensaries.

WALKER, J. SWIFT, M.D. St. And., F.R.C.S. Edin., M.R.C.S. Eng., Medical Officer of Health of Hanley, Smallthorne, and Stoke-on-Trent Rural Districts.

WALKER, W., M.R.C.S. Eng., House-Surgeon to the General Infirmary, Doncaster.

WALKER, W., M.R.C.S. Eng., Medical Officer of Health, Kirkleatham, and Medical Officer of the Convalescent Home and Surgeon to the Children's Hospital, Coatham.

WALSH, T. W., F.R.C.S. Eng., Senior Surgeon to the Worcester General Infirmary.

WALSHAM, W. J., M.B. Aberd., F.R.C.S. Eng., Assistant Surgeon and Demonstrator of Practical Surgery at St. Bartholomew's Hospital, Surgeon to and Surgeon-in-Charge of the Throat Department at the Metropolitan Free Hospital, and Surgeon to the Royal Hospital for Diseases of the Chest, London.

WALTER, W., M.D. Dub., Obstetric Surgeon and House-Surgeon at St. Mary's Hospital and the Manchester and Salford Lying-in Hospital.

WARD, E., M.R.C.S. Eng., House-Surgeon at the General Infirmary, Leeds.

WARDEN, C., M.D. Aberd., F.R.C.S. Edin., Senior Honorary Surgeon to the Birmingham Ear and Throat Infirmary, and Honorary Surgeon to the Birmingham and Midland Counties Orthopaedic and Spinal Hospital.

WARNER, F., M.D. Lond., M.R.C.P. Eng., Assistant Physician to the London Hospital and to the East London Hospital for Children.

WATNEY, H., M.D. Cantab., M.R.C.P. Lond., Assistant Physician and Joint Lecturer on Physiology at St. George's Hospital, London.

WATSON, W. SPENCER, M.B. Lond., F.R.C.S. Eng., Surgeon at the Great Northern Hospital and Royal South London Ophthalmic Hospital.

WEBB, W., M.D. St. And., F.R.C.S. Eng., Senior Medical Officer of the Wirksworth Cottage Hospital.

WEBER, HERMANN, M.D. Bonn, F.R.C.P. Lond., Physician to the German Hospital, Dalston, E.

WEBSTER, J. A., M.R.C.S., House-Surgeon at the Royal Albert Edward Infirmary and Dispensary, Wigan.

WELLINGS, R., M.R.C.S. Eng., Medical Officer of Health and Medical Officer to the Cathrington Union, Coatham, Hants.

WEST, J. G. U., L.R.C.P. Lond., M.R.C.S. Eng., Honorary Medical Officer to the North Staffordshire Infirmary, and Medical Officer to the Workhouse, Stoke-on-Trent Union, Medical Attendant to the Staffordshire Nursing Institution, Stoke-on-Trent.

WEST, J. FITZJAMES, F.R.C.S. Eng. (Exam.), Senior Surgeon to the Queen's Hospital, and Consulting Surgeon to the Dental Hospital, Birmingham.

WHERRY, G. E., M.B., F.R.C.S. Eng. (Exam.), Surgeon to Addenbrooke's Hospital, Cambridge.

WHIPHAM, T. T., M.B. Oxon., F.R.C.P. Lond., Physician and Lecturer on Pathology, and Physician in Charge of Department for Diseases of the Throat, at St. George's Hospital.

WHITEHEAD, W., F.R.C.S. Edin., Surgeon of the Manchester Royal Infirmary, and Surgeon to the Railway Passengers' Insurance Society.

WHITSON, J., M.D. Glasg., Extra Dispensing Surgeon to the Royal Infirmary, Glasgow.

WICKHAM, R. H. B., F.R.C.S. Edin., Medical Superintendent of the City Asylum, Gosforth, Newcastle-on-Tyne.

WILKINSON, J., M.D. St. And., L.R.C.S.I., Senior Surgeon to the County Infirmary, Limerick.

WILLETT, A., F.R.C.S. Eng., Surgeon and Instructor of Probationary Nurses at St. Bartholomew's Hospital, Surgeon to the Metropolitan Convalescent Institution, Walton-on-Thames, and St. Luke's Hospital for Lunatics, London.

WILLIAMS, A. F., L.F.P.S. Glasg., Medical Officer of Health of the Brixworth Rural District, Northamptonshire.

WILLIAMS, A. WYNN, M.D., Physician to the Samaritan Free Hospital for Diseases of Women and Children.

WILLIAMS, EDWIN W., F.R.C.S. Edin., Medical Officer of Health to the Bedwellty Rural District, and Abertillery Urban District, Newport, Mons.

WILLIAMSON, J. M., M.D. Edin., Surgeon to the Royal National Hospital for Consumption, Ventnor, and Medical Officer to the Bonchurch Convalescent Home of the Royal Hants County Hospital.

WILLOUGHBY, E. F., M.B. Lond., M.R.C.S. Eng., Medical Lecturer at the Church Mission College, Islington, and Honorary Medical Officer to the Holloway and North Islington Dispensary.

WILLS, C., M.R.C.S. Eng., Medical Officer of Health for the Southwell and Worksop Rural Districts, and Mansfield Urban District, Nottinghamshire.

WILSON, A., M.D., Demonstrator of Zoology and Comparative Anatomy at the Edinburgh School of Medicine.

WINTER, W. H. TRIMNELL, L.K.Q.C.P. Irel., M.R.C.S. Eng., House-Surgeon of the General Hospital, Wolverhampton.

WOAKES, E., M.D. Lond., M.R.C.S. Eng., Consulting Physician to the Luton Cottage Hospital, Senior Surgeon to, and Surgeon of the Ear Department at, the Hospital for Diseases of the Throat Golden-square, London.

WOLFE, J. REISSBERG, M.D. Glasg., F.R.C.S. Edin., Ophthalmic Surgeon and Lecturer on Oculistic Surgery at the Aberdeen Royal Infirmary, Surgeon to the Glasgow Ophthalmic Institution.

WOLFENDEN, R. NORRIS, M.B., Lecturer on Practical Physiology at Charing-cross Hospital.

WOOD, W., M.D. St. And., F.R.C.P. Lond., Physician to the St. Luke's Hospital, E.C.

WRIGHT, A., M.R.C.S. Eng., Medical Officer to the Second District of the Romford Union, and Medical Officer of Health to the Romford Rural and Urban Districts.

WRIGHT, C. J., M.R.C.S. Eng., Senior Surgeon to the Leeds Public Dispensary.

WRIGHT, G. A., M.B. Oxon., F.R.C.S. Eng. (Exam.), Surgeon to the Children's Hospital, Pendlebury, Manchester.

WYBRANTS, J., M.D. Aberd., F.R.C.S. Eng., Coroner for the South-East Division of Somerset, and Honorary Consulting Physician to the Shepton-Mallet Hospital.

YOUNG, W., M.D. Durh., M.B., Medical Officer of Health of the Malton Rural and Union Districts.

## METEOROLOGICAL READINGS.

## Medical Diary for the ensuing Week.

## Monday, Nov. 27.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10½ A.M. each day, and at the same hour.  
 ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M. each day, and at the same hour.  
 METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.  
 ROYAL ORTHOPEDIC HOSPITAL.—Operations, 2 P.M.  
 ST. MARK'S HOSPITAL.—Operations, 2 P.M.; on Tuesday, 9 A.M.  
 MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Drysdale, "On the Treatment of Syphilis."—Dr. Routh, "On the Difficulty of Diagnosing true Syphilitic Disease in the Female, and the Nature of its Contagion."

## Tuesday, Nov. 28.

GUY'S HOSPITAL.—Operations, 1½ P.M., and on Friday at the same hour.  
 WESTMINSTER HOSPITAL.—Operations, 2 P.M.  
 WEST LONDON HOSPITAL.—Operations, 3 P.M.  
 ANTHROPOLOGICAL INSTITUTE OF GREAT BRITAIN AND IRELAND.—3 P.M. Dr. G. W. Parker, "On the Language and People of Madagascar."  
 ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Dr. F. Warner, "On Spontaneous Postures of the Hand considered as Indications of the Condition of the Brain."—Dr. C. H. Ralfe, "On Seventeen Cases of Epilepsy treated with Sodium Nitrite."—The President will show a series (belonging to Dr. H. von Ziemssen) of full-sized Photographs of the Face, showing the action of particular muscles under electrical excitation, throwing light on the various distortions of the features.—Preparations and Drawings illustrative of Epilepsy will also be shown from the Museums of the College of Surgeons, St. Bartholomew's, St. George's, University College, and other museums.

## Wednesday, Nov. 29.

NATIONAL ORTHOPEDIC HOSPITAL.—Operations, 10 A.M.  
 MIDDLESEX HOSPITAL.—Operations, 1 P.M.  
 ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.  
 ST. THOMAS'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.  
 ST. MARY'S HOSPITAL.—Operations, 1½ P.M.  
 LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.  
 GREAT NORTHERN HOSPITAL.—Operations, 2 P.M.  
 SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2½ P.M.  
 UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at the same hour.—Skin Department: 1.45 P.M., and on Saturday at 9.15 A.M.

## Thursday, Nov. 30.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.  
 ST. BARTHOLOMEW'S HOSPITAL.—1½ P.M. Surgical Consultations.  
 CHARING-CROSS HOSPITAL.—Operations, 2 P.M.  
 CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and on Friday at the same hour.  
 HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M.  
 NORTH-WEST LONDON HOSPITAL.—Operations, 2½ P.M.  
 HARVEIAN SOCIETY.—Harveian Lectures: Mr. Henry Power, "On Ophthalmic Medicine and Surgery in relation to General Practice."

## Friday, Dec. 1.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1½ P.M.  
 ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 2 P.M.  
 ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.  
 KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.

## Saturday, Dec. 2.

KING'S COLLEGE HOSPITAL.—Operations, 1 P.M.  
 ROYAL FREE HOSPITAL.—Operations, 2 P.M.

## Notes, Short Comments, and Answers to Correspondents.

All communications relating to the editorial business of the journal must be addressed "To the Editor."  
 Lectures, original articles, and reports should be written on one side only of the paper.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."

W. H.—1. As regards the public vaccination, no official regulations can be made to meet such a case and, hence, we know of no remedy.—2. As regards the pauper returns, under the General Order of the Local Government Board, February 12th, 1870, it is incumbent upon all district and workhouse medical officers of health, appointed since February 23th, 1870, to furnish the medical officer of health with returns of pauper sickness and deaths, as well as to notify the outbreak of dangerous infectious disease. A similar obligation has been imposed by the Board's order, June 14th, 1870, upon medical officers of district schools appointed after June 24th, 1870. If a district medical officer was appointed before February 28th, 1870, then the procuring of the pauper returns of sickness is a matter of arrangement. The clerk to the guardians usually supplies it, and, according to a memorandum issued by the Local Government Board in June, 1882, "It is competent to the sanitary authority, whether rural or urban, to pay a reasonable sum to the clerk to the guardians for the supply of this information."

M.E.C.S. and L.S.A.—Guardians have the power, though preference is generally given to persons with the double qualification. Has the M.D. not also the degree of C.M.?

## INCANDESCENT CARBON LAMP.

To the Editor of THE LANCET.

SIR,—For the last few weeks I have used almost daily a small incandescent carbon lamp, to illuminate the cavity of the mouth during my dental operations. I have fitted it into a vulcanite cup and covered it for safety with a glass shade. Placed in the mouth the vulcanite cup acts as a prop to keep it open, and the lamp gives a bright light exactly where it is wanted, without producing undue heat. I have mounted another at the end of a vulcanite catheter, and am sure that in this form it will be most valuable for general surgical use, as it may be easily applied to many various purposes, both for the examination of interior cavities and in deep-seated operations, &c. The lamp has been made expressly for me by the Swan Electric Light Company, and I shall be pleased to show it in use here between the hours of four and five in the afternoon.

I am, Sir, faithfully yours,

Wimpole-street, Cavendish-square, W., NATHANIEL STEVENSON.  
 Nov. 18th, 1882.

## "AN IRREGULAR PROCEEDING."

A CORRESPONDENT directs our attention to the following extract from the *Western Morning News* of Nov. 13th:—

"Through some unaccountable delay somewhere no inquest has been held yet on the body of Edward James, who died suddenly when returning from Tavistock on Tuesday night. The body is lying in a small cottage, where he had lodged, and which is inhabited by a large family and other lodgers. For the sake of the health of the family and lodgers, in common decency the inquest should be held and the burial take place at once." With respect to this case, our correspondent gives the subjoined particulars:—"On Tuesday evening I was sent for to see the deceased, who, I was told, had fallen down dead on his way from Tavistock, and in company with another man. The deceased was buried yesterday, and no inquest has ever been held touching his death. I have not even received a communication from anyone on the subject of the death. I may further state that Edward James had only been in this neighbourhood for about six weeks, having come here from Somerset to work on the Princetown railway. I have every reason to believe that he had seen no doctor since his arrival here. Surely this is a most irregular proceeding!"

A *Doubly Qualified Assistant's* letter is too long for insertion. Moreover, its tone is somewhat discourteous.

Dr. Pavy's communication arrived too late for publication this week.

## EMIGRATION.

To the Editor of THE LANCET.

SIR,—Would you kindly give me space in your columns to ask the profession what chance has a medical man of "getting on" in Winnipeg, Australia, or New Zealand, and would it be advisable to go out to any of those places, and if so, which? I shall be thankful for any information any gentleman can give me on the above question.

I am, Sir, yours truly,

November 18th, 1882.

PHYSICIAN AND SURGEON.

## GERMAN MEDICAL STATISTICS.

REFERRING to a statistical work recently published there were at the end of 1882 in Germany 17,923 doctors. Of this number about one fourth were resident in Prussia, this preponderance arising in part from the fact that in Berlin there were 1048, being at the rate of 9.53 per 10,000 inhabitants, while the proportion for all Germany was found to be 3.87. There were 239 societies, numbering in all 10,024 members, which were specially engaged in the defence of professional interests. The number of associations dealing with the science of medicine was 68, comprising 7696 members. There existed 17 bodies, with 7306 members, for the promotion of sanitary measures. Military doctors had 8 societies of their own.

## A TEST FOR BUTTER.

A new apparatus devised by Ostén for discovering the extent of adulteration which may exist in butter would seem, according to the description in the *Corpo Gras Industriels*, to be effective and reliable in its action. The sample which is tested is melted and the butyric substance it contains is conducted into a graduated tube, composed of glass and so arranged as to show at a glance the percentage of genuine butter. This proportion would not, it is remarked, represent less than 85 per cent. of the total milk, and water should only be found in a ratio of from 1 to 5 per cent.

**District Medical Officer.**—It is true that medical officers are often, and sometimes systematically, annoyed by the frivolous complaints brought against them for alleged neglect of duty. There is, however, no remedy. The solicitor's advice is doubtless sound, though hard to take placidly. Better bow to the inevitable. The consciousness of having shown all due diligence and humanity in the performance of his important functions is, it would seem, the Poor-law medical officer's only reward.

**B. H.**—There have been many portraits of the late Sir James Simpson. The particular information desired by our correspondent would doubtless be given by Professor Simpson, of Edinburgh.

The length of *Mr. Le Page's* letter precludes its insertion in our present number.

## PAINFUL MICTURITION.

To the Editor of THE LANCET.

SIR,—I would feel much obliged if any of your readers would offer some suggestions as to the treatment of the following case. Mrs. W., aged thirty-eight years, confined of last child about twelve years ago, and who has had good labours, began to suffer from frequent desire to micturate about nine months ago. She has been forced to keep her bed for the last six months in consequence of frequent micturition with a peculiar dragging pain, which sets in immediately after passing water and is of a most acute character. This pain generally lasts about ten minutes, but at times is almost continuous. The pain, which is most severe at night, or when being in the erect posture for some time, is referred solely to the neck of the bladder. On introducing a sound, acute pain was complained of as soon as the instrument touched the urethra and also on its touching any part of the surface of the bladder. She has passed blood on four occasions, each lasting over a few days. The urine, normal in reaction, is highly lumbinous, cloudy, containing pus and flaky or shreds and gritty matter. After standing for twenty-four hours a membranous, almost transparent, substance stretches from the top to the bottom of the fluid. There is no pain in the back nor thigh and no stoppage in passing water. I failed to detect any stone in my examination. I have tried alkalies, hyoscyanus, bromides, pareira, morphia, camphor internally, and also injecting the bladder with carbolic lotion (which gave rise to much pain) without effect.

I am, Sir, yours very truly,

PUZZLED.

November 13th, 1882.  
**Mr. J. Atkinson Hooker.**—We fear that our correspondent cannot claim more than the ordinary fee.

**L. S. A.** may consult the article in our Student's Number, published Sept. 9th.

**Aliquis.**—We do not prescribe. Any surgeon would advise in the matter.

## "INUNCTION IN SCARLATINA."

To the Editor of THE LANCET.

SIR,—Under the above heading a discussion has been carried on in medical journals for the last few weeks, to which I am desirous of adding my testimony.

During the outbreaks of scarlet fever in Fulham Small-pox Hospital, where there has been no provision for the isolation of such cases, I have successfully treated them year after year in the wards occupied by small-pox patients without the chance of spreading the disease to the others. The plan I adopted was to bathe the patients every morning and anoint their bodies with carbolic oil of the strength of one to twenty for weeks. Their nursing, bed-linen, &c., were kept separate as far as the circumstances allowed. I never had reason to think of any evil results arising from the inunction of the oil. Moreover, the limitation of the disease to a few cases, with such precautions as were taken at Fulham Small-pox Hospital, gives an argument against the hypothesis of aerial infection. Since then it has been my practice to use the same in private cases with the advantage of controlling the spread of the disease. I have now one case under my treatment progressing towards recovery.

I am, Sir, yours obediently,

MONTAGUE D. MAKUNA, M.B.C.S., L.R.C.P. Lond.  
Dock-street, E., November 20th, 1882.

## EXAMINATIONS AT THE ROYAL COLLEGE OF SURGEONS.

THE last examination for the present year for the diploma of Membership of this institution was commenced on the 10th instant, when the following questions on Surgical Anatomy and the Principles and Practice of Surgery were submitted. The candidates were required to answer at least four, including one of the first two out of the six questions between 1.30 and 4.30 P.M.:

1. Mention the parts in contact with the gluteus maximus muscle.
2. Name in order the structures that must be divided in amputation of the fore-finger at the metacarpo-phalangeal articulation.
3. Mention the principal circumstances in which an abscess is likely to be followed by a sinus or fistula.
4. Mention the causes of epididymitis. Give the course, diagnosis, and treatment of the disease.
5. Describe paronychia and its treatment.
6. Describe the clinical characters, especially in reference to diagnosis, of epithelial ulcer of the tongue.

The following were the questions on Midwifery and the Diseases of Women. Candidates were required to answer three out of the four questions from 12.30 to 2 o'clock:—

1. What is the effect of ergot upon the process of labour? In what circumstances would you administer this drug, and what conditions would you regard as contra-indications to its use?
2. In what circumstances is decapitation of the foetus required? How would you perform this operation?
3. What are the causes of chronic ovaritis? By what symptoms and signs would you recognise this condition? How would you treat it?
4. State the common causes, and describe the preventive treatment, of mammary abscess.

The following were the questions on the Principles and Practice of Medicine. The candidates were required to answer three out of the four questions, including No. 4, between 2.30 and 4.30 o'clock:—

1. Describe the symptoms and course of typhoid fever, touching upon its distinctions from diseases which resemble it, its treatment, and post-mortem appearances.
2. Indicate the symptoms, course, complications, and treatment of rheumatic fever.
3. What are the pathological conditions and clinical results of extravasation of blood within the cranium?
4. State the composition, doses, and use of the following preparations:—Pulv. Ipecacuanhe co., pulv. jalapæ co., pulv. kino co., pulv. claterii co. Name the preparations, with their doses, of the following drugs, and give the general effects and uses of each drug:—digitalis, antimony, arsenic, colchicum, and aconite.

**Mr. S. P. Smith.**—The destruction of cultivated organisms by carbolic acid has been repeatedly proved, but we are not aware that it has been verified in the case of the tubercle bacilli, to which we presume our correspondent refers. There is no reason, however, to suppose that it is not true of these also.

**Mr. J. L. Shadwell.**—We are unable to refer our correspondent to any authenticated report of the death of an adult from the bite of the common viper.

**Carmen.**—We are not aware of the Haslam process having been applied to a hospital, and doubt much whether it could be done.

**M. E. C. S.**—The percentage mentioned is too high for those permanently disabled.

**Mr. Thomas McGrath** had better consult a surgical instrument maker.

**Mr. Wm. Hardman.**—Messrs. Illce and Horne, 31, Aldermanbury.

**C. E.**—Cassell's books on the subject.

## UNQUALIFIED ASSISTANTS.

To the Editor of THE LANCET.

SIR,—To prevent misapprehension will you give me a corner in your columns to say that the judge, in the case you published last week, gave a verdict against the plaintiff, not because his assistant was unregistered, but because he was unqualified. This is not new law. I know of a case where, before the passing of the Medical Act in 1858, a plaintiff lost a large account because his assistant, who had partly attended the defendant, was not a L.S.A., as he had described himself to be. Moreover, if a qualified man employs an unqualified assistant and palms him off upon his patients as a qualified man he is liable to indictment, and if the assistant help to maintain this fraud he, also, is liable to indictment. How, then, can it be possible to recover for attendance given under such circumstances as these if the defence be conducted by what is difficult to find in these medical cases—a competent lawyer?

Partnership will not protect unqualified practice. In one of the early prosecutions by the Medical Alliance a verdict was obtained in the County Court against a defendant. This defendant subsequently endeavoured to protect himself by entering into partnership with a M.R.C.S. and L.S.A. The Alliance again prosecuted, but this time in a superior court, when a second verdict was obtained against him, and the action cost him altogether not less than £150. He then sold his business to a trebly qualified man. Of course, a registered practitioner may, under a deed of partnership, agree to share his professional income with, say, a cobbler, but, unless he dare a prosecution, the cobbler must stick to his cobbling and take no part in his partner's doctoring.—I am, Sir, your obedient servant,  
Stockwell-road, S.W., Nov. 20th, 1882.

R. H. S. CARPENTER.

## REPORTING CASES OF SUICIDE.

G. P. asks our opinion on the following case:—"Called to a case of suicide (gun-shot wound of chest), known only to friends. Is there any necessity, from a legal point of view, to inform the police? I am not sure whether any penalty attaches for not reporting such an occurrence." The case is somewhat novel, but we believe that our correspondent will be doing his duty to himself, his patient, and the public by keeping a discreet silence. Suicide is a felony, but it is scarcely possible that a medical man, by trying to rectify the effects of the felony, of which he was entirely ignorant till after the fact, could be regarded as *particeps criminis*.

CAN MIDWIFERY FEES BE CLAIMED WHEN ATTENDANCE IS NOT ASKED? *Indignant* writes to us that in a case where he was clearly engaged, but not sent for, the judge disallowed his fee. This is the glorious uncertainty of the law. Our correspondent must, referring to the other question raised in his letter, make patients clearly understand whether they are being treated on dispensary terms or not.

*Mr. Banks*.—It is impossible for a man to kill himself by simply holding his breath, for the automatic efforts to inspire prove too strong for the will to resist; but the head might be held under water till unconsciousness supervened, and the automatic efforts to inspire would then be ineffectual, and death would result.

## "SINGLETON'S OINTMENT."

To the Editor of THE LANCET.

SIR,—One of your correspondents, signing himself "Rusticus," asks for the composition of Singleton's golden ointment. As it is so valuable and generally recognised a remedy, I have much pleasure in enclosing the original receipt, from which I have always prepared it. It requires care in making and to be well stirred until cold, when it will come out of a brilliant golden colour. To make the ointment full strength the butter and oil must be reduced one half. It would be well to publish the receipt in your journal.

Singleton's original receipt was obtained about forty years since from the occupier of the house in Fleet-street, nearly opposite St. Dunstan's Church, where Singleton lived.

I am, Sir, yours very truly,  
ALBERT NAPPER.

R Hydrargyri, ʒss.; acid. nitric., ʒvss.; butyri [without salt], ʒvj.; oleum olivæ, ʒiv. Hydrargyrum in acido primum liquus; dum liquorum adhuc calentum, butyro et oleo simul liquefactis; misce.—N.B. This is half diluted.

H. D. F.—The discussion of medical questions in the lay press is no doubt highly objectionable, as we have frequently pointed out.

*Enquirens*.—To make sure of the facts, and to take a good opportunity of protesting.

## IODINE STAINS ON BODY-LINEN PRODUCED BY INUNCTION OF IODIDE OF POTASSIUM OINTMENT.

To the Editor of THE LANCET.

SIR,—I was somewhat astonished a few days since, on visiting a patient, by the nurse showing me the under-linen, which was covered with large spots having the characteristic colour and odour of iodine. The patient had been recently confined of a seventh month child, which died a few hours after birth, and had been rubbing iodide of potassium ointment, with camphor, over the mammae to arrest the abundant secretion of milk. The linen, I was assured, contained no starch, and the patient exhibited no symptoms of iodism. Will you or some of your readers inform me if such appearances as the above are common?

I am, Sir, yours faithfully,  
Whitstable, Nov. 13th, 1882. J. W. HAYWARD.

## CONSTRUCTIVE MURDER.

A BIRMINGHAM CONTEMPORARY, in an article commenting on the case of a chemist condemned to death at the Stafford Assizes for causing the death of a woman by using an instrument to procure abortion, incidentally says: "It is well known to the initiated that there are qualified surgeons in every large town who, for a consideration and on reasonable assurance of secrecy, will render the aid that is required." We beg to tell our contemporary that we neither know nor believe such a statement to be true.

COMMUNICATIONS, LETTERS, &c., have been received from—Mr. Savory, London; Dr. Tompkins; Mr. Biggs, London; Mr. Meadows, Hastings; Dr. O'Connell, Sioux City; Mr. E. Carr, Wakefield; Dr. Ryley, London; Dr. Sinclair Thompson, London; Dr. Nicholls, Chelmsford; Mr. Albert Napper, Guildford; Mr. Turner, Norwich; Mr. N. M. Reid, Tunbridge Wells; Mr. Jennings, London; Mr. Tuckey, Tynemouth; Mr. Makana, London; Mr. Hamerton, London; Dr. Davison, Liverpool; Dr. Eben. Watson, Glasgow; Mr. Mallins, Watton; Dr. Macdougall, Carlisle; Mr. F. W. ## SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year.....£1 12 6 | Six Months .....£0 16 8  
TO CHINA AND INDIA ..... One Year, 1 16 10  
TO THE COLONIES AND UNITED STATES .. Ditto, 1 14 8

Post Office Orders should be addressed to JOHN CROFT, THE LANCET Office, 423, Strand, London, and made payable at the Post Office, Charing-cross.

Notices of Births, Marriages, and Deaths are charged five shillings. Cheques to be crossed "London and Westminster Bank."

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on page 2, which not only affords a ready means of finding any notice, but is in itself an additional advertisement. Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance. Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET. Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed. Advertisements are now received at all Messrs. W. H. Smith and Sons' Railway Bookstalls throughout the United Kingdom, and all other Advertising Agents. Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher.

Agent for the Advertising Department in France—J. ASTIER, 67, Rue Caumartin, Paris.

## Considerations

BEARING ON

### 3 PRESENT KNOWLEDGE OF FEVER.

A First Lecture.

BY WALTER MOXON, M.D., F.R.C.P.,

PHYSICIAN TO, AND LECTURER ON THE PRINCIPLES AND PRACTICE OF MEDICINE AT, GUY'S HOSPITAL.

GENTLEMEN,—In pursuance of the usual course, I have, by what is rather an abrupt change, to turn your attention to the subject of Fevers. I conceive that a teacher professing to teach the principles and practice of medicine must, when his subject is fever, proceed to explain the class what fever is from the point of view first of principles, then of practice. Speaking now very generally, I suppose that principles must here mean a consideration of what fever is in itself, and practice must mean what you do with fever when you meet it.

Taking the principles first, our question becomes, What is fever? Well, then, what is a fever? As I do not know sufficiently well to say offhand, I thought it best to look in a book, and I chose what I regard as the best recent work on medicine. In it I find the esteemed and accomplished author saying, "By the term fever is meant that abstract condition which is common to all so-called febrile disorders, and the presence of which gives them claim to that designation." Now I am always a little timid when dealing with anything that deliberately calls itself abstract, and I am ready to confess to you that I feel myself very insecure in abstract questions. There is an un-English lucidity—I might almost say an alien pellucidity—about them which stranges them from one's practical middle-class mind; so that, indeed, it is necessary for me to form a habit of militarising abstractions to that mind by clothing them in some concrete form, or at least by paralleling any puzzling ones with others better known to me. Let us do so in this case, and instead of fever suppose we put *heat*. We shall then perhaps get an idea as to how far our inquiry "What is fever?" is advanced by the definition I have quoted to you. Let us ask, What is heat? and answer in parallel terms: "By the term heat is meant that abstract condition which is common to all hot things, and the presence of which gives them claim to that designation." But really when I look at this definition I am afraid your physical philosophy will not be much enriched by such a piece of information.

Well, but what in its own nature is a fever? Be patient with me. Half the answer is often obtained, and the other half commanded, by asking the question rightly. Again, then, let us try the compass of the question as we just now tried the value of an answer by paralleling it in a better-known field of inquiry. Suppose we ask, What in its own nature is a horse? Now, you would not say, "By the term horse is meant the abstract condition common to all equine animals, and the presence of which gives them claim to that designation," for you will see that that really involves a fallacy. As other animals than the horse are equine, just as we shall presently see that other diseases than fever are febrile. Well, from the point of view of such unlimitedly general principles as would touch the nature of the things dealt with, What is the nature of a horse or of a fever? I must answer you that, in truth, we do not know the nature of anything in itself; we do not know the nature of our own bodies, nor even the nature of our own minds. In fact, we do not know what nature is. It is a growing, and we no more know how it comes about than our bones grow than the old ecclesiast did. Our language cannot fit itself to the processes and results of nature or growing. All we do is not nature, but fabric. And our readings of nature are in language of fabric; even when they are not unconscious fabrications. The laws, or, as Bacon termed them, "forms" of unliving things, are perfectly expressed by the language of science, which follows their *a posteriori* progression with measure and rule. But the laws or forms of living things are not *a posteriori* causes, but *a priori* reasons for existence. So that, if I may so speak, dead nature exists *a posteriori*, No. 3092.

but living nature *a priori*. And human language must in some sort be read backwards if we are to catch the meaning of the life of living things. The genius of Darwin has left us a formula which works somewhat like the integral calculus works, so that by its means reasoning belonging to straight line *a posteriori* nature is turned at an infinitude of little tangents, and so fitted to the immeasurable, unknowable curved lines of the forms of *a priori* living nature. But we must beware, lest with the aid of this powerful theory of natural selection we find ourselves contentedly reasoning in circles. This is not one of my easy ideas, and lest it should be too pellucid I will proceed to clothe it in a concrete form, and ask you to observe how, even in your simplest readings of nature, even in the description of the simplest anatomical facts the discrepancy between the nature process and the mental process at once appears in its primitive simplicity. Thus you say the biceps muscle arises from the scapula and is inserted into the radius; but, in fact, the biceps muscle grows in its place, and grows in continuity with the scapula and radius, and it never arose from the one or stood in a past participle relation of the verb to insert as regards the other. You cannot conceive how it really comes about that the continuity of bone and tendon and muscle grows into being, and when you proceed to state a history of it you can only do so in such terms as your mind and its language are capable of, and so you speak as if the growing of it were much the same thing as your making of it would be, and talk as if you, or somebody like you, had made first a scapula and then sprung a biceps from it, and afterwards fastened it on to the radius.

Thus, it is true that in dealing with living nature our language tends to put us mentally athwart the facts of the case, even as concerns things that you can realise and handle, like the biceps muscle. But inasmuch as what we have to know of and to do with the biceps is comparatively simple, we are not led into any practical inconveniences, for the biceps, capable of that measurement which constitutes science, is there before your eyes, to keep you steady and prevent your imagination from playing its tricks. But our question is of the nature of a fever. And we find our last new book on medicine defining fever as an abstract condition which gives claim to a designation; and you will at once see that a thing of that kind is not so easily got hold of as the biceps. And I am saying all this so that we may understand each other as to the proper character and the limits of our inquiry; and not carry it too far, lest we should feel dissatisfied because we cannot know of fever what we do not know of the biceps, and that we may not lose ourselves in wandering after questions as to the nature of fever, such as could not be answered regarding the most tangible and ponderable living objects.

We begin, then, if you please, with the clear knowledge that we cannot know the nature of fever, and so we will not ask it. We must, then, resign so much of what we, in the most general view, may seem to profess in the term principles of medicine.

But it is now time that we take up a more positive position and endeavour to learn what the principles of medicine in relation to fever really are. Yet it may be well to quite clear up this word "principle," lest it should contain anything vague and pretentious. The word "principle" is very ambiguous in its signification; you find it in the sphere of morals with the most noble absoluteness of meaning in the whole range of language—as when you say "a man of principle." And there are sciences in which the principles are abstract and absolute, as in the case of mathematics. And thus the term "principle" assumes to us, since we all have been taught morals and have learnt mathematics, an absoluteness coming from our prior experience of its use; so that the word "principle" claims to express an absolute masterfulness of obligation. And in expounding the principles of medicine with regard to fever, we naturally look for some general principles about fever whose obligation is absolute, and masterful, and commanding. But, in truth, it must be confessed that when we come to deal with the facts of living nature, we are obliged to let go the commanding style in any application of the word "principle." In short, we have to seek for our principles patiently and laboriously amongst the facts of the cases. And, indeed, we have to find our principles amongst the facts, and we have to be content with the most commonly and generally recognisable facts and consider them our principles. Thus in physical science, and especially in the physical science of living things, the greater and more absolute

significance of the word "principle" fades away, and principles are selected from the dust of facts, and when the science is of living nature, sometimes of somewhat fuliginous facts. Perhaps it is as well that we should note this change in the connotation of the word "principle" in an age which, listening to its great eloquent biologists, and eloquent physiologists would teach its boarding-school girls their principles from the physiology books. As if to try, in our remote civilisation, the social force of that principle whose invention and advocacy proved so dangerous to Socrates, "virtue is a knowing." Some watch must indeed be kept lest the dusty signification of principle in physical science should quite take the place of that originally pure idea of principle which made man human. Of course if the only object of teaching is knowing, and the only object of education the expansion of the knowing machinery, then it may not much matter what you teach, and, perhaps, the more that is known the better. And as leading biologists are enthusiastically anxious to have what they themselves know used as a pattern on the minds of the young, and as unclued middle-class fathers have a dimly lighted reverence for knowledge they do not possess, and a worthy ambition for their offspring to be better scholars than themselves, these fathers send their children to take pattern of the biologist without themselves quite knowing what it all amounts to, and the modern biologist in his full accomplishment makes such a good picture. But, then, it is not a good picture, but a good pattern, that you want, if you are going to take copies, and a good picture is not always a good pattern; and to estimate the goodness of a teaching you have to go not by the graceful refinement which embellishes what is taught, but by the rough and, perhaps, rude imprint which will be received by the minds of some vulgar young creatures incapable of refinement but very capable of physiology.

Ay, and what a world it will be "in the coming by-and-by" when there is a little more too much of this comely creation of physiology. Indeed, I was tempted not many mornings ago to ask a question which in truth it would need a great shock to force upon my mind. The question whether the spread of biological science can have so increased even to our highest clergy the comparative importance of this sublunary bodily life that the minutest corporeal details of them should be found in the columns of the daily press, so that, for instance, you could not touch your penny paper without finding close to the leaders a full medical description of the profoundest and most cloakworthy secrets of the organisation of your revered archbishop set out in rather large type. Nay, if I may so speak, without having his renal secretions running upon the columns of your *Standard* until you were obliged to drop it from your fingers to finish your breakfast.

But to return from this digression to the principles of medicine with regard to fever. Principles, I say, in physical science are merely the most generally realisable facts, the most certainly and constantly realisable facts, and general principles are facts from which other less general facts are found to depend. And now I shall digress again, for if principles depend upon facts it is very important that these facts should be what are commonly called real facts, an expression which, as it infers the practical recognition of unreal facts, may serve a significant purpose. For since principles are merely general facts, where shall we go if our very principles should prove to be unreal facts, as they have in the history of our wandering art so often been, though, of course, not now? I do not mean that there is any doubt of our principles now; but we must really beware in physiology of unreal facts.

The beauty of modern physiology is that it does try hard to beware of unreal facts; and the conduct of physiological inquiry is in such able hands, and guided by such clear heads, that the danger of unreal facts is at its minimum. Surely, this is the case when men like Burdon-Sanderson and Lander Brunton represent the prevailing spirit of physiological inquiry. No better questioners of nature ever lived. But this goodness of their questioning is unhappily irrelative to any value in their answering, and we may see why of necessity this must be so. Their clear heads keep them to the asking of such questions as can be answered, and they are unsparing of effort whilst labouring for the answers, in spite of undeserved public odium. And, indeed, the future of physiology lies in the pursuit of answerable questions; but, alas! for the practical usefulness of the science that is compelled to choose its questions without

regard to the value of its answers. True it is that pure science is noble, and feels its nobility with a just pride. Have I not heard of a mathematical club whose toast is, "Pure mathematics, and may they never be of any use to anyone"? Perhaps, too, we may have a physiological club, with a like warmth-of-ardour toast, and if so the hope may seem in progress of achievement; for, led by their questions, the ablest inquirers are but increasing the pile of unwanted answers. The tree of physiology is full of fruit nowadays; but, of course, it bears only such fruit as it can bear, and tries to ripen in the very tepid sunshine that surrounds it.

I trust your clinical digestion will not be spoilt with the sound, but unripe, fruits of physiology. I beg you will not think that I am speaking against physiology. Having, however, just escaped from the chair of *materia medica*, and so become a disinterested person, I may be allowed a *tu quoque* against the great aggressive modern science, whose arch-teachers would give you no time to learn your drugs so that you should share their noble knowledge of snails. But intensifying the knowledge of a thing does not increase the real value of the thing known, which, if petty, is still petty, however scrutinised. I think some one should protest from a chair of Medicine against those who darken counsel with the dust of their knowledge; who invade your limited time with accounts of artificial diseases which, like those artificial serpents of Pharaoh's magicians, have all but the spontaneity which characterises life. But what do the physiologists care for life? when life is to them nothing but the de-clension and conjugation of protoplasm—truly, in a vast confusion of tenses. So that the life indeed becomes to the physiologist even less than meat; a mere epiphenomenon of meat. I speak thus boldly because I am here to tell you that the principles of medicine are general clinical facts, and its practice requires you to be strictly utilitarian in your medical philosophy. In short, to employ again an analogy I used before, I have to find the calculus which will follow the curve round from mere fact truth to usefulness; and these may be at a tangent one to the other. But we in our pursuit of the principles of medicine in regard to fever—that is, in the pursuit of the most general facts of the human fevers, we are at a great disadvantage as compared with the experimental physiologists; for, whilst Dr. Burdon-Sanderson can always compose the bases of his experiments, and so be sure of real, if of useless, facts, we of the principles of fever have to watch for our facts when they chance to appear, and very often we have to watch long; so that our progress is apt to be like the progress of astronomical science with regard to such heavenly bodies as only appear occasionally, like comets and meteors; and we may observe that astronomers have somewhat speculative views about those bodies.

The course of a long life will give you but insufficient opportunities of observing the general facts of many diseases. And you must begin early. We may now thank the College of Physicians for having given you six months' medical ward work instead of the miserable allowance of three, which scarcely enabled you to learn the medical use of your senses. You cannot begin too early. You have heard of Hippocrates; he wrote a book in which he put down his clinical observations, and I hope you will learn to place a high value on that book. But if you do not get beyond his first observation, he will do you good if you take that observation well to heart. The first observation he thinks a clinical observer should make is this, "life is short." This truth thus sounds to us from the most distant past, and will reach into a future we shall not reach. It is the first truth the clinical observer hears spoken to him by his most ancient predecessor, and the Royal College of Physicians suggestively wears it on its escutcheon. Do not forget it. The reason why it is so important is that you have to take advantage of chance repetition in order to compare one disease with another. So go and see as many good cases as you can in the wards.

All the great clinical observers began early to observe. This is true of Sydenham, and the first Jenner, of Bright, of Addison, and of Hilton, and amongst those living now. It is true of the Jenner who still adds lustre to a great name, and of Owen Rees, Gull, Hutchinson, Wilks, and of all earnest clinical observers. For you study an art wherein you cannot go when you wish to look at the objects of your study, but as to which you must keep your eyes about you, that you may see things when they chance to appear, and each man amongst you must obtain the greatest possible amount of direct experience of these principles or general

facts. For in dealing with real things, and especially in interfering with the health, even if it be the grossly bad health of other persons, we must have a direct grasp of our principles, and this I have shown you to be the same thing as to have a direct knowledge of the general facts, so that what we say may be as little as possible second-hand, for to get in the habit of speaking or acting at second-hand is to lose the power of meaning, and the value of a doctor varies according to what he can himself mean to do, and do. And when you say a thing at second-hand you do not quite mean it. Of course, when you say a thing is, you mean that it is. But if you have not seen that it is, your meaning that "it is" is necessarily less directly grounded. And, in fact, if you say a thing is, and mean it all you can from hearsay knowledge, your "is" comes—as the hearsay is more distant—to be really worth no more than its value as a copula in an abstract proposition, such as the "is" in the statement that "a griffin is a dragon with wings." The value of the copula varies as the directness of the utterer's knowledge. You can only mean when you know and believe, and from this digression I wish to lead you back with a firmer grasp of the greatest truth a young medical mind can inform itself upon. The great truth, that inasmuch as your future is of value to others in proportion as you can mean to do and mean to say, and inasmuch as you can have no proper meaning from indirect knowledge, you must know the principles or general facts of your art at first hand and for yourself.

Our question has now transformed into, What are the general facts common to the several kinds of fevers? Now, I am really afraid that you will accuse me of deliberately drawing you aside into obscure questions whenever we approach a clear one; but though I am speaking to very various minds, various in capacity and tendency, some of which will think I am talking nonsense, and others will think that there is much more of profundity and importance than there really is in it all, yet I must follow my own judgment of what is needful, and ask you now to consider, in an abstract way, What do you mean by a kind of fever? This word kind is so constantly employed by every one of us with variations in its import, that it is worth our while to clearly understand in what sense we may rightly use the word "kind" when speaking of a kind of fever, as compared, say, with the sense in which we use it when speaking of a kind of inflammation. It is well not to use this important word vaguely. Shall I tell you a little anecdote to impress one of its possibly clear significations on your memory? The anecdote involves, I regret to say, a confession; but it was in the days when I was young, and not under proper self-control. I chanced to be placed, for the purpose of tuition, with a gentleman of an entomological turn of taste. The delight of this gentleman in discovering a new fly inspired my always sympathetic nature with the wish to afford him such a gratification. But new kinds of flies could not always be found, especially flies new to him, so one very hot afternoon it struck me to give him his favourite pleasure by a somewhat indirect and factitious proceeding. Inspired with this purpose, I caught a large housefly and rolled it carefully in the carmine powder and set it free, taking care that it was well within sight of my instructor. The fly was seen, and I do not think I ever witnessed such eagerness of pursuit. The day, as I said, was hot, and the fly was lively, so that my instructor, and I at second-hand, had good sport. When the insect was at length captured, I may tell you at once that, after handling the insect for a moment, my master concluded that it was not a distinct kind of fly; yet in the mere matter of colour it had as much ostensible claim to be considered a new kind as *digitalis purpurea* to be considered a distinct kind from *digitalis alba*. But the reason why he never thought of allowing the red fly to be a distinct kind was that he at once understood when he touched it how the fly came to be red, and, I am sorry to say, shrewdly guessed who made it so. Now if, instead of finding red powder on the fly, he had caught such a fly red in a manner he could not explain, he would have pinned it out on cork, and have called it "*musca rubra*," or something equivalent. What I want you to perceive is, that a usual and a true ground of distinction of kind is the existence of differences which you are unable to explain; and perhaps, indeed, that would be the only general philosophical ground for distinction of kind, were it not that with reference to living things another system of facts affords narrower and more special and proper grounds of distinction of kind. I mean in the power which living things have of reproducing their kind which power of

reproduction is the basis of zoological and botanical distinctions of kind. But even amongst cattle breeders, who are most concerned in this question, the idea of kind belongs rather to resemblance than descent, as you may note from their speaking of a casually varying individual of a flock or herd as being out of kind.

(To be concluded.)

## THE PATHOLOGY OF THE BLOOD IN INFLAMMATION.

By JAMES T. R. DAVISON, M.D. EDIN.,

SENIOR HOUSE-SURGEON, ROYAL SOUTHERN HOSPITAL, LIVERPOOL;  
LATE RESIDENT PHYSICIAN, ROYAL INFIRMARY, EDINBURGH.

(Concluded from page 885.)

THE morphological origin of fibrin formation has been established by Dr. Norris. Of this he has afforded both positive and negative evidence; for he has photographed the invisible corpuscles in the act of becoming fibrin,<sup>1</sup> and he has also found that a pure filtrate of blood, containing no morphological elements, does not undergo coagulation.<sup>2</sup> According to Dr. Norris, the cells which become fibrin are the primary lymph cells, the invisible corpuscles (nuclei of the former), and the faintly visible undeveloped red corpuscles (a further development of the second). Partial confirmation of this origin of fibrin formation is adduced by Bizzozero, who ascribes the formation of fibrin to his blood-plates (primary lymph-corpuscle of Norris), and by M. Hayem, who ascribes the same formation to his so-called hæmatoblasts. But both these observers look upon their respective elements rather as determining centres of fibrin formation. That fibrin is present in the inflammatory exudation has been shown by Dr. Burdon-Sanderson, who states that in inflammation of the mesentery the fibrin can be seen on the surface of the membrane.<sup>3</sup> It being established, then, that fibrin is present in inflammatory exudation, and that fibrin is a rearrangement of cells and nuclei of the blood, it follows that in inflammation these fibrin-forming cells and nuclei migrate from the capillaries as well as the leucocytes, and this migration of fibrin-forming elements must be accompanied by an increase of their number in the blood, on the same principle that a migration of leucocytes determines an increase of leucocytes in the blood. The question arises, How are we to know that the fibrin-forming elements are in excess in the blood? Now, there can be little doubt that the hæmatoblasts described by M. Hayem are the granules caused by the disintegration of the undeveloped red corpuscles.<sup>4</sup> No one has seen these granules in the circulating blood, but they have always been observed in shed blood. Dr. Norris has shown that human blood examined on the cold stage of the microscope is free from these granules, while it contains them when examined under the ordinary temperature. This is pretty clear evidence that the granules can be formed after the blood is shed. But Dr. Norris has given positive evidence of their formation, for he has photographed the undeveloped red cells in the act of becoming disintegrated. The evidence afforded by micro-photography cannot be gainsaid. What cannot be discerned by the unaided microscope can be brought out by photography; therefore this kind of evidence is superior not only in that it reveals objects just as they really exist, but in that it discloses more of them. The fact that these granules are formed after the blood has been shed does not exclude the possibility that they may also be formed in the circulation under pathological conditions; indeed it seems very probable that this does actually take place sometimes, as evidenced by the enormous quantities of granules present in certain states. Whether, however, these granules be found in or out of the circulation, or, as is more probable, under both conditions, it is evident that they are formed from the undeveloped red corpuscles; hence we may fairly take the number of granules as an index of the number of undeveloped red cells, and, as these latter cells constitute one of the fibrin-forming group of cells, we may roughly

estimate the number of fibrin-forming elements in the blood by the number of granules present on the microscopical slide.

In acute large abscesses I have sometimes found the granules present in great abundance; at other times, though in excess of the normal, this excess has not been marked. I found in some cases of acute abscesses, where the excess of granules was marked, that after the abscess was opened the granules diminished in quantity, and after a time again increased. This fact is very interesting, as showing that the increase of the granules in inflammation is determined by two principles. In the first instance the determining cause is the same as that which obtained in the case of leucocytes—namely, a migration of fibrin-forming elements from the capillaries, and a consequent demand by the blood for more of these elements. It may be objected that as no fibrin is seen in pus, therefore there can be no migration of the above elements. Certainly if we examine pus from an abscess we do not find any fibrin in it, but then what about the pyogenic membrane? What is the pyogenic membrane? In the first place it may be remembered that Dr. Burdon-Sanderson has shown that inflammation is not "altered nutrition," as was once supposed, but that it is an "arrest of nutrition"; that it is not a constructive, but a destructive process.<sup>5</sup> This fact would seem to disprove the idea that the pyogenic membrane is a connective tissue formed during, and as a result of, the inflammatory action; and even supposing that it were a connective tissue, its expansion as the abscess increased in size could not be accounted for, as ordinary connective tissue is incapable of the expansion that would take place in a large increasing abscess. Moreover, if the pyogenic membrane were connective tissue, an abscess could not enlarge, for this tissue would prove an effectual barrier to the migration of leucocytes. The explanation must therefore be that the pyogenic membrane is formed by the fibrin-forming elements which have migrated from the bloodvessels, and become conglomerated together on the surface of the abscess; that it is, in fact, the analogue of the layer of fibrin seen on the inflamed mesenteric surface. In the same manner must be explained the formation of membrane on the inflamed pleura and pericardium. The fact that these membranes often become organised does not destroy the assumption that they are formed from altered elements which have migrated from the blood, for the organisation may be effected in the same way as Professor Hamilton describes the organisation of a sponge inserted in a wound—viz., by the bloodvessels of the serous membrane being pushed into the substance of the fibrin. Thus we can account for the increase of granules seen in the blood during the active period of abscess formation. When the abscess is opened tension is relieved, and migration is at least partially arrested, hence the decrease of granules in the blood at this stage. But the granules increase again, and this second increase I believe accords with the hæmatoblastic crisis of M. Hayem. M. Hayem has found (and his observations have been confirmed by M. Reyne) that about the time of the crisis of acute diseases these granules are increased in the blood, and their excess is ascribed to an effort of nature to repair the blood after the decrease is over.<sup>6</sup> The state of the system after the healing of an acute abscess is somewhat similar to its condition at the crisis of an acute disease. In either case there has been tissue destruction owing to the high temperature, and therefore in either case a reparation of the blood would be profitable. The reparation of the blood would naturally be effected by an increased discharge of blood elements into the circulation, and as these blood elements would consist of undeveloped red cells, and as moreover one of the stages of the undeveloped red cell disintegrates into granules after the blood is shed, therefore we can easily account for the increase of granules seen in the blood at this period. But the first increase of granules I hold to be determined by a different cause altogether—viz., by the migration of fibrin-forming elements, for this increase takes place during the active period of the inflammatory process, and therefore before the repairing influence comes into force. At the beginning of pneumonia, pleurisy, peritonitis, cystitis, laryngitis, and bronchitis I have found an increase of the granule, generally a slight one, and a larger increase I have noticed about the time of the subsidence of the disease. These two increases, running into one another

and apparently one, I believe to be as distinct from each other as they are in the cases of acute large abscesses. The reason why the two increases appear to be only one is that the first is generally slight, and a decrease of it would not be easily noticed, and this holds good also for some cases of acute large abscess. But in those cases of acute large abscesses where the first increase is very marked after the knife has been inserted and tension relieved, the decrease of the granules becomes obvious, as does also the secondary increase which takes place later on. There appears to be thus two waves of increase of granules in the blood in acute inflammation—the first being the manifestation of the supply of fibrin-forming elements of the spleen and probably lymphatic glands consequent upon the demand made by the migration of these elements; the second a manifestation of the supply of blood-cells by the same organs consequent upon the demand made by the system to repair the blood after the disease is over.

In conclusion, I do not mean to infer that the leucocytes of the blood are only increased during the active period of inflammation. It is well known that they are increased in leucocythæmia and after severe hæmorrhage, and I have found them increased in yet other conditions. What these other conditions are have yet to be ascertained. I have not a sufficient number of cases to justify me in making any generalisation with regard to them, but I claim for the principle enunciated above an important place as an element in the diagnosis of inflammatory lesions, nor do I wish to state that the granules are only increased during the inflammatory process and at the crises of acute diseases. I have elsewhere endeavoured to show that causes which interfere with the development of the red cells give rise to an increase of the granules in the blood, the increase in these instances being due, not to an extra supply of cells by the blood-forming organs, but to an arrest of development, whereby a good many cells do not become fully hemoglobinised red cells, and as a good many of these disintegrate into granules, therefore under these conditions we find the granules in the blood increased in quantity.

### STONE IN THE BLADDER; RETENTION; SUPRA-PUBIC ASPIRATION; EXTRA- VASATION; DEATH.

By C. A. INNES, M.D.,  
SURGEON TO HER MAJESTY'S PRISON, HULL.

W. L—, aged seventy-five years, came in as a prisoner on June 26th. He seemed a healthy, strong, well-nourished man, but stated that he had been troubled with gravel for the last ten years, and had to micturate every few minutes, night and day. Passed a No. 6 gum catheter, and found no stricture, but great enlargement of the prostate gland and irritability of the urethra. He applied every day at the surgery, and got a draught of solution of potash, hyoscyamus, and sweet spirits of nitre, which gave him considerable relief. About three ounces of slightly clouded urine were drawn off on July 8th, and tested with heat and nitric acid, but no albumen could be detected. On the 16th the symptoms were more urgent, and he was ordered, in addition to the usual draught, a hot hip-bath. On the 17th he was reported as having had diarrhœa the whole night. I found him very prostrate, and complaining of great pain over the pubes, and of being able to pass his urine only by drops. He had a hot bath, and was at once admitted into the infirmary, and the following is the entry in the case-book.

July 17th: Attacked with diarrhœa during the night; urethra very irritable, and bleeds freely when an instrument is introduced; No. 6 silver catheter was passed with difficulty, but there was no urine in the bladder; complains of pain in the lower part of the abdomen when manipulated, especially over the left iliac fossa; his penis is very painful when touched. Prescribed an astringent mixture, one ounce, to be repeated every hour if necessary, with hot fomentations to the abdomen and the perineum. Ordered four ounces of brandy with low diet, and one pint of beef-tea.—18th: Very restless during the night: passes water very frequently, an ounce at a time; diarrhœa checked; to repeat fomentations,

<sup>5</sup> Lumleian Lectures, 1882. Lecture I.

<sup>6</sup> Archives Générales de Médecine, Janvier, 1880, p. 123, Janvier, 1882, p. 104.

d have rice-water to drink, as he complains of thirst; tongue dry and furred.—19th: Slept better; bowels again subsides during the night; he has less irritation of the bladder, but is feverish; his face is flushed, and he seems very restless and uneasy. Ordered astringent to be repeated, and poultices to be applied over the abdomen.—20th: Patient remains much the same; he passes his water in dribbles; he rests better at night, and his bowels are quiet; to continue treatment.—21st: Has passed no water since yesterday evening; on examination there was a large accumulation of urine in his bladder, extending as far as the umbilicus; attempted to pass a No. 6 silver catheter, but was stopped by prostate, which was found on examination to occupy nearly the whole space of the outlet of the pelvis. P.M.: Dr. Robinson kindly saw the case with me; after considerable difficulty we passed a prostatic catheter, but failed to draw off the urine; tried by injecting warm water to clear the catheter of clots, and also by fixing the nozzle of the aspirator to the catheter, but beyond the smell of decomposed urine nothing was sucked up; the catheter appeared as if wedged tightly in the bladder. 3.30 P.M.: All attempts to relieve the bladder per urethram having failed, we aspirated above the pubes, and only about one drachm of highly decomposed urine was drawn off.—22nd: Patient is in a very critical state; no urine has passed naturally for thirty-six hours; he has been partially delirious and very restless; towards morning his stomach became irritable; no change in the size of the abdominal tumour; has now got congestion of the base of both lungs. Dr. Robinson again saw the case with me.—23rd: The patient died at 5 P.M.

Mr. Henry Thompson, by order of the coroner, conducted the post-mortem examination, and has kindly placed his notes at my disposal.

*Autopsy, twenty-three hours after death.*—Body well nourished. Rigor mortis complete; blueness on depending portions. Head and chest not examined. Abdomen: One inch and a half above the pubes was noticed a punctured wound, the edges of which had made no attempts at union. Abdomen much enlarged, hypogastric and both inguinal regions appeared to be occupied by a doughy irregular mass, more prominent on the left than on the right side. Abdominal walls and omentum contained a considerable amount of fat. General peritonitis of intestines, especially on the left side, both gluing the intestines to each other and also to the bladder and pelvic walls. Liver natural. Kidneys large and pale, and studded with cysts. Between the bladder and the pelvis, behind the peritoneum, extending into the substance of the abdominal walls, and dipping down into the pelvis, was a mass of gangrenous cellular tissue infiltrated with urine, distended with gas, and containing some small calculi. On dissecting out the bladder a mass of calculi (105 in number, and weighing 3 oz. 69 grains) was found sacculated in a distinct cavity to the left of the bladder, but communicating, through an opening large enough to admit two fingers, with the bladder itself. The summit of this sacculus had ulcerated or sloughed through, and the urine and some of the calculi had escaped out of it into the gangrenous mass previously described, and of which they were the cause. No calculi were found in the bladder itself. The walls of the bladder were hypertrophied, and the mucous membrane rugous, and in a sloughy state. The urethra was natural, but the prostate gland was much enlarged.

The case is interesting from the number of calculi sacculated and undetected, and from the puzzling and grave symptoms which developed themselves on the 21st July—viz., the suppression of urine, the size of the tumour simulating a distended bladder, and the unsuccessful attempts to evacuate the bladder. It is pretty clear that peritoneal inflammation had commenced on the 17th, probably occasioned or intensified by the diarrhoea which he had on the night of the 16th, and that perforation and extravasation took place on the night of the 20th. The tumour felt must have been the thickened wall of the bladder, with the inflamed visceral matters, and glued to it.

At Leicester last week the sale by auction of goods seized for non-payment of fines for neglect of vaccination was made the occasion by anti-vaccinationists for a demonstration almost amounting to a riot. The presence of some forty police constables was hardly sufficient to maintain order.

## ON THE INTERNAL ADMINISTRATION OF CHRYSOPHANIC ACID IN PSORIASIS.

By H. E. CAUTY, M.R.C.S. &C.,

SENIOR SURGEON TO ST. GEORGE'S HOSPITAL FOR SKIN DISEASES, LIVERPOOL.

IN May last there appeared a rather long article in THE LANCET, in which the internal administration of chrysophanic acid in psoriasis was sufficiently favourably mentioned as probably to induce many gentlemen to give this medicine a trial. The list of remedies having any special cutaneous action is so limited, that any new one would, I think, be gladly welcomed by the profession generally, and it was the attributed possession of this specific power by the acid that merited attention in the paper above named, for it was stated that the idea of the internal use of chrysophanic acid was first suggested by observing that in a case where both legs were affected with psoriasis, both got equally well, though the acid as an ointment was only rubbed into one of them, the inference drawn being that the absorption of the acid and its subsequent constitutional action cured one leg as well as the other; the other deduction, that the acid had nothing to do with the disappearance of the disease, was not considered. There were a good many cases mentioned in THE LANCET, but on examination all were either fragmentary, incomplete, or unsatisfactory, but one, which was that of a boy seven years old, with psoriasis of two years' duration, who, after six weeks in hospital, was cured of the disease by gradually increasing doses of chrysophanic acid, taken not without sundry inconveniences, until at last two grains three times a day were supported. In this case, as in all the others, no mention is made of the state of the pulse, which in psoriasis is so important, for no case of this disease occurs in which the pulse is not either slower, smaller, or weaker than it ought to be, and any medicine which either ameliorates or cures this disease improves the pulse in either rapidity, volume, or strength. The favourable case was also young. In youth psoriasis is very common and comparatively less persistent than in after life, disappearing and returning eccentrically, from causes often slight and untraceable. However, it having been stated that chrysophanic acid had some good qualities, it was tried in many cases, of which the three following are examples:—

CASE 1.—M. T.—, aged seventeen, engaged in the boot trade. Tongue rather white and irritable, countenance flushed and thick; pulse 72; psoriasis guttata on arms, with some patches of twelve months' duration; very thin; regular.—July 19th: Half a grain of chrysophanic acid in sugar of milk three times a day after food.—23rd: Patches fainter; complexion clearer; tongue cleaner; was gripped after taking the first powder.—20th: Took two powders; more gripping and sickness four hours after the second powder. Bowels opened three times.—21st: Took two powders, was very sick, and had pyrosis. Treatment changed to solution of bismuth, aloes as a purge, and then arsenic. This case was not encouraging, but as there were symptoms of irritable stomach at starting it might have been exceptional.

CASE 2.—R. B.—, aged nineteen, machine worker, made her first appearance at the hospital on May 12th. This was a well-marked case of psoriasis nummulata; the tongue was rather white and bowels confined; conjunctivæ slightly yellow. She had in addition to the eruption four hard subcutaneous lumps in the calves of the legs, feeling like knotted veins, around which there had been some exudation, and which knots were extremely painful (thrombosis); pulse 72, weak. She was ordered potash and ammonia with podophyllin, which she took until June 2nd, when the swellings in the legs had nearly gone and the tongue was clean, the eyes being still somewhat tinged; bowels open.—June 2nd: On that date she began to take a quarter of a grain of chrysophanic acid three times a day.—5th: Conjunctivæ clearer.—9th: Dose increased to one-third of a grain.—11th: Scales falling off, swellings gone, tongue clean; pulse 84, full and soft; not at all the pulse of psoriasis. I now began to have hopes that there was some real benefit to be obtained from the acid, as there were no fresh spots, and the symptoms (though this stage has often been reached by many medicines)

were generally better. The dose was increased to five-twelfths of a grain.—16th: These hopes were arrested, as though the bowels were open twice a day and the tongue clean, there were some fresh spots, slight papules, with some flatulence. Dose increased to half a grain.—19th: Dose three-quarters of a grain; tongue clean, bowels open, rash somewhat paler; pulse 84, weak; flatulent colic. — 23rd: Dose one grain.—26th: No fresh spots, rash paler; hepatic pain under right shoulder.—30th: The legs have no more spots, but there is increased formation of scale; there are also fresh patches formed on the elbows, arms, and hands; pulse 72, fair; tongue clean; bowels open twice a day; these are now so sensitive that directly she takes her tea in the morning she has to hurry to relieve them. Notwithstanding that it appeared as if the chrysophanic acid had reached the utmost stage of toleration, I was desirous of seeing if a larger dose would have some effect on the eruption, and consequently having told her to discontinue the powders if the symptoms required it, the dose was increased to one grain and a half three times a day.—July 3rd: The powders excited great vomiting, and the scaly formation very much increased; pulse 72, full and soft; discontinued powders on July 1st. She was then ordered a carminative mixture, and afterwards arsenic, and is now nearly well. Notwithstanding that these cases showed no special cutaneous action of chrysophanic acid, yet thinking that there was some evidence of increased biliary secretion apart from simple purgative action on July 29th, I tried it in the next case.

CASE 3.—C. M.—, a widow, aged fifty-seven, a large flabby fat woman with two large bright-red patches of psoriasis, exfoliating large scales, covering one elbow and one knee, each patch being three inches square. Tongue foul and coated; pulse 72, weak; bowels confined. She began with half a grain doses of acid on July 28th, increased to three-quarters on July 31st.—August 1st: There is no improvement in either the rash or the tongue; the bowels are purged twice a day, and the powders have each time produced vomiting; the conjunctivæ are still mahogany colour.

*Observations.*—The results obtained in these cases were not such as to encourage further trials, nor to confirm the supposition that there was any specific cutaneous action; on the contrary, it leads to the deduction that in the successful case published in THE LANCET the good result must have been due to continuous purging, and if this deduction is correct, then there are other medicines whose action is equally efficacious, and at the same time free from those irritating properties which characterise chrysophanic acid. In three other cases in which this was tried it acted so immediately as an emetic that it would be absurd to consider them in connexion with a constitutional action. In the second case where the drug was tolerated better than in the others at the time when, if any, a specific benefit ought to have been manifested, the disease increased in virulence. It is possible that in future therapeutical works the acid will be quoted as a remedy for psoriasis, and in consequence it may be tried by many gentlemen whom the persistence of the disease has sorely puzzled; it is with a view of pointing out what results may possibly be expected that the foregoing cases have been recorded and sent for publication.

*Note.*—The name chrysophanic acid is retained in the above observations, but I am informed that the proper name is chrysarobin. This is the active principle or one of the active principles of rhubarb; and I notice in the *Pharmaceutical Journal* the active principle of senna, supposed to be cathartine, has been resolved into three substances, one of which is chrysarobin. The action of the so-called chrysophanic acid resembles very much that produced by senna and all its preparations on some individuals.

THE SURGICAL AID SOCIETY.—The Lord Mayor presided at the annual meeting of the subscribers to this Society, held at the City Terminus Hotel on Monday. The report stated that 1442 men, 2024 women, and 703 children had benefited by the charity during the past year. The amount expended in surgical appliances and surgeons' fees had been £4006. But for the receipt of a legacy of £1307, there would have been a considerable balance on the wrong side. His lordship regarded this state of things as unsatisfactory, as he thought legacies should go to the reserve fund.

## TREATMENT OF CHRONIC DYSENTERY BY LARGE INJECTIONS OF NITRATE OF SILVER SOLUTION.

By GEORGE E. POST, M.D.,

PROFESSOR OF SURGERY IN THE SYRIAN PROTESTANT COLLEGE; SURGEON  
TO THE JOHANNITER HOSPITAL, BEYROUT.

THE patient is a European lady who has lived for about eight years in Syria, aged about thirty years, of healthy constitution, the mother of three healthy children. Partly as the result of nervous prostration, and partly from lactation, she was attacked in the latter part of last autumn with pains in the back of the head and some confusion of the mental faculties. These symptoms, with persistent sleeplessness, continued until the beginning of the spring of the present year, when she was attacked with diarrhoea, which gradually assumed a dysenteric character. At the time when I first saw her, July 28th, her state was as follows:—Great general debility and nervous prostration, nausea, which was in part due to a mixture of catechu and other astringents which had been administered with a view of checking the diarrhoea; characteristic dysenteric evacuations, accompanied with severe colicky pains and abdominal rumbling and uneasiness. She was not at that time taking any precautions in diet, nor confining herself to bed. There was no elevation of temperature, but the expression of countenance was haggard and worn. She was also much discouraged about her state, and harassed by sleeplessness, and in despair of recovery. The tongue was somewhat roughened by the astringents which she had taken.

I commenced the treatment by fifteen-drop doses of castor-oil, a strict milk diet, rest in bed, and ten-drop injections of laudanum in starch to quiet the tenesmus. This treatment was continued for forty-eight hours, with the effect of bringing away a few scybala, and relieving to a certain extent the tenesmus and nausea and slightly improving the character of the discharges. On the afternoon of August 1st an injection of three pints of water containing forty-five grains of nitrate of silver was prepared. The syringe was not, however, in good order, and not more than a pint entered the bowel. This was retained four or five minutes. It brought away with it mucus, greenish faecal matter, a few scybala, and a little blood. A good deal of pain followed, and lasted for about an hour before it quite passed away. Shortly after the first motion she had another free from scybala. An hour and a half later another more copious, with considerable pain; half an hour later a small one with little but mucus; a little later some bloody mucus. As pain continued a laudanum and starch injection was administered. Twenty minutes later she had a small brownish stool, with a little mucus. After this she slept for three-quarters of an hour, and woke to have a small mucus passage, after which she vomited. An hour later a small motion. Still an hour later a brownish stool with some greenish admixture and little mucus. Five other motions occurred during the next seven hours, the last looking like ordinary liquid faeces. In the morning she was sick and vomited, but soon after, despite a few small motions, felt stronger. She took her milk and limewater better, and occasionally a teaspoonful of brandy. The headache had nearly passed away, and she slept fairly between the motions. No fever or quickening of the pulse. Abdominal pain much lessened. The history of the second day is briefly as follows:—Motions: 9 A.M.; 10, small but natural; 12.30 P.M., small but natural, with a little greenish slime; 1 to 3, four small motions, the last with specks of mucus; 3.30 to 6, two motions, the last small but natural; 7.30, small quantity of mucus. As there was some tenesmus without any passage an injection of starch and laudanum was administered, and half an hour later she fell asleep, and slept five hours, and awoke hungry. During the day the sickness of the stomach was much lessened, and she took and retained sufficient nourishment. In general she felt much better all through the day and night. During the remainder of the night of the second day she slept with little interruption. On the morning of the third day, at 6.30, she had a natural motion, but with it a little mucus and blood, and slight abdominal pain before passing. At 7 A.M. a copious natural motion; 1.45 P.M., small but natural, with a little mucus; 2.15 to 6, two motions like the former of this day; 6.15, a few

scybalæ; 8.15, an injection of laudanum and starch (ten drops) was administered, after which she slept till 2 A.M., and again from 3 to 6 A.M., when she had a motion, not fluid and natural in colour, with the addition of a small patch of bloody mucus. The fourth day, at 7.15 A.M., a small natural motion; 9, a little mucus; 3 P.M., a small natural motion, after which two pints of the above-mentioned solution of nitrate of silver were injected. She would not allow the whole three pints to be thrown in on account of the pain which they caused. The injection was retained less than a minute. It brought away with it less than the first, but some scybalæ, less than before. She continued to have evacuations for three-quarters of an hour, the last being mucus without blood. The pain did not wholly cease for an hour and three-quarters, and then only after a laudanum injection. She continued weak and nauseated until 7 P.M., when she began to feel quite easy, and continued so until 9.15 P.M., when she fell asleep. After an hour of restless sleep she fell into a natural slumber, in which she continued uninterruptedly until morning. No motions since 4.15 P.M. The fifth day was a good one. She was able to knit a good part of the day. She had one motion between noon and 1 P.M., with a little mucus, and another at 2 P.M. quite natural, semi-solid. She slept soundly during the night. She seemed to have caught a little cold towards morning, from insufficient covering, and complained of soreness in the bones, &c. It passed off, however, early in the morning of the sixth day. At 2 P.M. of the sixth day she had a small motion, quite solid. Began to long for food and experienced a hungry feeling, which the milk only took away for a short time. She took large quantities of the milk, but was not satisfied. She had neither pain nor ache, and the tongue was much cleaner. On the eighth day she began to take a little breast of chicken and soft-boiled eggs, and day by day her diet was improved. On the fifteenth day she had had no return of diarrhoea, had been up for three afternoons, walking a little about the room, and feeling stronger each day. Ten days having since elapsed without any further tidings, it may be inferred that she is now quite well.

As the treatment had to be conducted, after the first visit, by correspondence, at a distance of fifteen hours by messenger, some delay unavoidably occurred in advising the successive steps of the management of the case. Had the patient been within reach, I should have given the first injection a day sooner, and the second two days sooner. The return to a more nourishing diet might also have been slightly accelerated. On the whole, however, the case leaves little to regret, and nothing to desire. The very small quantity of laudanum required after the inauguration of the nitrate of silver treatment is most instructive. The easy and continuous sleep after such prolonged insomnia is also a feature worth noting. Any treatment which can cure so aggravated a form of dysentery as this one in so short a time, and with no drawback but the temporary pain of the injection, is an invaluable resource to the practitioner.

Beyrouth.

## ON A CASE OF SIMPLE FRACTURE OF THE STERNAL END OF THE CLAVICLE INTERNAL TO THE RHOMBOID LIGAMENT.

BY G. OWEN WILLIS, L.R.C.P., L.R.C.S. ED.,  
SENIOR SURGEON TO THE MONMOUTH HOSPITAL.

J. E., aged fifty-four, a labouring man, was admitted into the Monmouth Hospital on July 18th, 1881. He stated that two hours previously he slipped off a hayrick, fell heavily on his outstretched right hand, and also struck his right shoulder. On examination a simple fracture of the sternal end of the right clavicle was discovered within a quarter of an inch of the sternal head of the bone. The direction of the fracture was obliquely downwards and outwards. The outer fragment rode high in the neck from the action of the clavicular fibres of the sterno-clavicular mastoid muscle and the weight of the arm. The fractured end of the outer portion was very sharp, and threatened to lacerate the skin. The inner fragment presented no marked sign of dis-

placement, was freely movable, easily depressed, and on pressure the sensation was conveyed to the finger of its being loose and rolling. He had fractured the sixth and seventh ribs in front of and close to their angles. My efforts to adapt the broken ends of the clavicle were but partially successful. Apposition of the ends was gained when the right arm was raised and the fingers of the right hand

FIG. 1.

touched the left ear, the point of the elbow being slightly tilted forwards by a pillow. Any attempt to fix the limb in this position was not tolerated for long. I had to content myself with slinging the arm and placing a pad of cotton-wool on the shaft of the clavicle; this last kept in position by strips of plaster crossing the chest from back to front. He had a sharp attack of pleurisy, and was

FIG. 2.

very restless, often getting in and out of bed, but recovered and was discharged convalescent on August 29th, 1881. saw him again on August 30th, 1882, when a photograph and cast were taken. The broken end of the outer fragment was rounded off and lessened by absorption, and he had fibrous union permitting of some movement. That morning had done a bit of stiff digging, and considered his recovery good one.

I have been influenced to publish this case at such length because fracture of the sternal end of the clavicle is rare, whilst fracture internal to the rhomboid ligament is very rare. Holmes, in his "Principles and Practice of Surgery," 1875, says, "it has not as yet been proved." Bryant makes no mention of the injury, and I am indebted to the kindness and courtesy of my old teacher, Mr. Henry Morris of the Middlesex, for the following references:—Hamilton refers to three cases (in a record of 105 fractures of the clavicle) in which the fracture was within one inch of sternum, and he says that in such fractures, which of course, within the fibres of the rhomboid ligament, there is but little displacement. Lonsdale mentions

case in a child three years old, which came under his care in the Middlesex Hospital, and which he regarded as a separation of the epiphysis. Malgaigne mentions two cases, in one of which the fracture was so near the sternum that it was difficult to say whether it was not a partial dislocation; the displacement was only trivial. There are two preparations in the Musée Dupuytren in Paris of fractures very close to the sterno-clavicular joint, and in both the displacement is considerable, and in both the outer fragment is thrown down and forwards. Hamilton, in a recent edition of his work, says he has had a case of fracture close to the sternal end, the specimen of which he showed to the New York Pathological Society. The man from whom the specimen was taken was forty-five years old, and the fracture, occasioned by a fall upon the shoulder, extended from the sterno-clavicular articulation upwards and outwards an inch and a half. The fragments were overlapped three-quarters of an inch, and were firmly united. The character of the accident was not recognised until after death. The specimen is now in the Bellevue Hospital. In the case I report there can be no doubt that the rhomboid ligament was ruptured, and it was remarkable that the displacement of the outer fragment, which was very considerable, was upwards and not downwards, as in the cases collated by Mr. Morris.

Monmouth.

### TONIC TREATMENT IN MITRAL DISEASE.

By J. BROWN, L.K.Q.C.P., L.R.C.S.I.,

HONORARY MEDICAL OFFICER TO THE BOLINGBROKE PAY HOSPITAL.

THE following case is interesting as demonstrating the benefit derived from a tonic treatment in a case of dropsy, with regurgitant mitral disease, enormously enlarged liver, and albuminous urine.

Mrs. B——, aged forty-nine years, a widow, came first under my care as a private patient in August, 1881. She was then suffering from rheumatic arthritis and bronchitis. She had a distinct mitral murmur of old standing; her liver was very much enlarged, coming down half way to the umbilicus; there was no ascites, but considerable oedema of the ankles. She was a free liver, her usual stimulant being Irish whisky. She improved under treatment, which was continued for about three weeks. I did not see her again until she came under my care at Bolingbroke Pay Hospital on April 4th last. She then presented the following symptoms:—The valvular murmur was very distinct; she could not lie down on account of difficulty of breathing; her liver was very hard, and extended half way between the umbilicus and the pubis; there was considerable ascites, and her legs were oedematous to half way up the thighs; her urine was scanty and very albuminous; her skin was slightly jaundiced; temperature normal. All stimulants were stopped, and she was treated from April 5th to the 15th with a mixture containing digitalis, squills, carbonate of ammonia, and gentian; as the bowels were confined, compound jalap powder, forty grains, was given when required. No improvement being apparent, and as she seemed weaker, on the 15th a mixture of tincture of perchloride of iron and tincture of digitalis, of each ten minims, with glycerine, was given three times a day after meals, and was continued for nearly three months, most of which time she was kept in bed. In August all dropsical symptoms had disappeared; the liver was much reduced in size about two inches below the ribs, and no trace of albumen in the urine. All treatment was then stopped, but she remained in hospital until Oct. 8th. For the last six weeks she was able to walk several miles a day, which she had not been able to do for some years, and when she left the liver was still smaller, no trace of albumen, and she was gaining flesh, and slept well in natural position. I think this case bears out some of the ideas put forward by Dr. Leech in his introductory lecture to a discussion in Medicine at the last meeting of the British Medical Association.

New Wandsworth.

KING'S COLLEGE, LONDON.—The Right Hon. Sir John Mowbray, Bart., M.P., D.C.L., has consented to pre-ide at the Annual Dinner of Associates and Students, to be held in the College Dining Hall, on January 17th, 1883. Mr. H. Courtenay Luck, A.K.C., F.R.G.S., of the College, is acting as secretary.

### A VACCINATING INSTRUMENT.

By CHAS. EDWARDS, A.B., M.D., F.R.C.S.

THE instrument resembles a miniature subcutaneous syringe with needle, but differs altogether in application and partly in construction. It is supplied by Messrs. Weiss and Son, who have constructed it beautifully and most satisfactorily.

The following instructions must be understood and carefully attended to:—

1st. Prior to operating apply the stoma or apical aperture of the needle to the lymph well exuded from the vesicle of the vaccinifer, then draw back a little the patent vulcanite piston. The instrument is thus charged somewhat beyond the basal aperture of the needle. The terms "basal" and "apical" I borrow from the extremities of the fang of the *neidr*. The instrument is now ready, by barely remoistening its point for as many instantaneous operations as are required.

2nd. How to operate: Do not gradually and slowly introduce the needle-point, as with the lancet, but quickly and with the *neidr* stroke just beneath the cuticle. By this method you infallibly introduce the lymph, no blood, as from the lancet puncture possibly intermingling, and the small quantity of air between the basal aperture of the needle and the perfect piston when compressed by the "stroke," causing a reflex wave or rebound of the lymph into the puncture, thus sufficiently resembling, at least, in effect, the action of the anguine compressing muscles. A start of the patient, or any possible unsteadiness of the operator, is provided against by a beautiful little guard on the needle, by which too deep a stroke is rendered impossible. There is to be no injecting or even meddling with the piston during the operation, simply remoistening the needle-point.

The following are the advantages of this instrument: Rapidity, perfect introduction of the lymph, the absence of unsightly scars or scarifications so revolting to parents, however much they may be thought meritorious by others.

One word as to vaccination from arm to arm. If we must use the now conventional term ferment, and if the vaccine lymph be or contain this ferment, though it is not my wish to christen it or make a raid on the Greek prepositions to denote its successive results, still as all ferments act within a certain range of temperature there can be no temperature so sure for vaccine lymph as that secured by its coming from one living arm to another.

Cheltenham.

### DISLOCATION OF THE UPPER AND LOWER ENDS OF THE LEFT HUMERUS BY THE SAME ACCIDENT.

By WILLIAM W. MOXHAY, M.R.C.S.,

SURGEON TO THE ROYAL BERKS HOSPITAL.

C. S——, aged fifty-six, was admitted into the Royal Berkshire Hospital seven weeks previous to Sept. 4th, 1882, with a dislocation of the left elbow, the condyles of the humerus being thrown forwards over the radius and ulna. He had been struck at the back of the upper arm by the handle of a winch which was rapidly revolving. I was then house-surgeon to the hospital, but a medical friend acting for me reduced the dislocation, and all went on so well that the man was made an out-patient in a few days. On the above date he appeared and complained of some stiffness of the shoulder-joint on the same side; this, he remembered, being seven weeks after the injury. I found the head of the humerus under the coracoid process, and I gave him one-grain and half-grain doses of tartarised antimony every ten minutes while extension of the limb was made downwards and outwards by means of pulleys. This went on for about half an hour, when he became deadly faint and could scarcely be kept in the chair. Extension was then suddenly left off and his elbow brought down over my knee as a fulcrum, when a sort of pop was heard and felt, and the bone returned to its natural position, only, however, to recede again to its acquired place. This was repeated once or twice on again replacing it, and at last we succeeded in

ing it in its proper position by a pad and bandages. He slowly recovered, and on Sept. 25th was regaining some of the upward movements of the limb, and at his own request was discharged.

As far as my knowledge goes this is a unique case, and I think it may prove of interest, especially to some of the younger members of the profession, who perhaps have never seen such use made of the powerful nauseant tartar emetic. Although it certainly enabled us to reduce the dislocation of the shoulder of seven weeks' standing, would not now advise a return to such a barbarous practice, though it had the sanction then of the revered name of Sir Astley Cooper. With chloroform (at the time we have mentioned only just peeping out as a future friend in such cases), *nous avons changé tout cela*.

### MIDDLESEX HOSPITAL.

SPONTANEOUS RUPTURE OF HEART; SURVIVAL FOR FORTY HOURS; AUTOPSY; REMARKS.

(Under the care of Dr. S. COUPLAND.)

FOR the following notes we are indebted to Mr. Alan E. Fate, resident physician's assistant.

W. T—, a gilder, aged sixty-five, was admitted into the hospital, Oct. 13th, 1882, with the following history. He had that morning gone to his work apparently in his usual health. About 11 A.M., while he was walking along the street, a heavy lamp fell close to and almost upon him. Although he was not struck he was startled very much. Three-quarters of an hour later, and after he had walked fully a mile further, he was seized with "a sudden pain all over the chest," and immediately after fell down in a fainting fit. He was found in this condition by a policeman, who at once took him to the hospital.

On admission into the Founder ward, at noon, he presented all the symptoms of the most extreme collapse. The whole body was cold and bathed in a profuse cold sweat. There was extreme pallor of face and lips; the radial pulse was only just perceptible, and the heart-sounds were quite inaudible. No increase in the cardiac dulness could be detected, but both lungs were evidently emphysematous. His mind was quite clear, as he answered questions readily, and gave a coherent statement of the morning's events. There was no paralysis. Within the next half hour he vomited several times, and there was constant tenesmus; once his bowels were opened well.

The patient was seen soon after admission by Dr. Coupland, and some internal hæmorrhage seemed probable. Cardiac rupture was surmised, though in the absence of any positive proof, such as an increase in cardiac dulness, and looking to his desperate state, a stimulant treatment seemed the only course indicated. A mustard poultice was accordingly applied to the præcordia, hot bottles were put to the feet, two ounces of warm brandy-and-water were at once administered, and the following mixture was ordered to be taken every hour: Spirits of ether and aromatic spirits of ammonia, of each half a drachm, and one drachm of syrup of tolu in water. Half an ounce of brandy was also given every three hours. Under this treatment the patient slowly, but steadily, rallied. At 5 P.M. the pulse was distinctly perceptible at wrist, and the heart-sounds were faintly heard at apex, free from bruit; surface of body comparatively warm. Temperature 96° 6'; pulse 76; respiration 25. About this time he complained of pain in the right ankle, and a fracture of the lower third of the fibula was detected and at once set. The fracture was believed to have occurred in the syncopeal attack. At 11 P.M. the same night the pulse was full and strong, 96; heart sounds moderately loud; lips and

face a fair colour; body and extremities warm. The stimulants were diminished in quantity and frequency, but still continued.

The next morning (Oct. 14th) the following note was made:—"Temperature 98° 6'; pulse 84. Slept at intervals during the night; has completely rallied from collapse. Skin warm; pulse of good volume and steady, but hard; heart sounds fairly well pronounced. There is some bulging of the left front of the chest in the præcordial region." Strict rest and stimulant treatment were continued, and all went well till 6 A.M. the following morning (15th), when, after a good night's rest, the patient became suddenly collapsed and died.

At the autopsy, which was made by Dr. Fowler, the following conditions were found: The cartilages of the third, fourth, and fifth ribs on the left side were prominent and arched. Those on the right side were flattened. All were calcified. On opening the pericardium about one ounce and a half of fluid blood escaped, and the heart was seen to be invested with blackish-red blood-clot, having a smooth outer surface. The clot was not adherent to the parietal pericardium. This clot was separable into two distinct layers, the outer of a rather paler tint and firmer. Each layer was removed separately, and found to weigh about seven ounces, some soft black clot at the back of the sac being weighed with the inner and probably most recently extravasated portion. The anterior surface of the heart showed a considerable excess of sub-pericardial fat. On turning the heart over, a rent half an inch long was seen in the posterior wall of the left ventricle, two inches and three-quarters above the apex and one inch to the right of the posterior coronary artery, having an oblique direction. A probe passed through the rent emerged into the left ventricle, just behind the apex of the posterior papillary muscle. The posterior coronary artery could be felt as a rigid cord, and the pericardium having been dissected off, it was seen to be extremely atheromatous and calcified. A branch of the vessel (not found) had apparently ruptured, as there was some blood extravasated beneath the pericardium and deeper in the fat and muscular tissue around the vessel for a distance of three and a half inches. The anterior coronary artery was also atheromatous. The right cavities contained some post-mortem clots, and the left ventricle also contained a small post-mortem clot. The mitral and tricuspid valves were somewhat thickened and fibrous; the aortic valve was atheromatous. All were probably competent. The muscular tissue of the heart was soft, brown, and greasy; that of the right ventricle encroached upon by the subpericardial fat. The aorta was atheromatous. Both lungs were emphysematous, and very œdematous.

*Remarks by Dr. COUPLAND.*—Perhaps the fullest information concerning Rupture of the Heart in literature is that given by Dr. Quain in his Lumsdian lectures (THE LANCET, 1872, i. p. 460), where he states that in 77 out of 100 cases there was fatty degeneration of the heart wall, and that 63 of the patients were above sixty years of age. He also points out what all writers, from Morgagni downwards, have noticed, that the exciting cause of the rupture is some sudden mental excitement or physical effort. In each of these particulars the case above recorded conforms to the general rule, but it may be added that until the day of the attack (which was distinctly referable to a violent mental shock) he had suffered no symptoms pointing to the existence of cardiac disease. Yet the coronary arteries were advanced in calcareous degeneration and there was considerable adiposity of the heart wall as well as true fatty degeneration. The case also resembles the majority in the lesion being in the left ventricle, but it is somewhat exceptional in the position of the rent, which in most cases has been found in the anterior wall, either in the region of the apex or close to the septum. In this case the rupture, which formed an oblique slit, occurred in the posterior wall at some distance from the septum, and about midway between the apex and base. This localisation of the lesion was, no doubt, determined by the disease of the coronary artery and its branches impairing the nutrition of that part of the wall. The case is further of interest in the prolongation of life after the occurrence of rupture. According to Dr. Quain, "in 71 out of 100 cases . . . death was sudden, occurring within one or two minutes. One patient, however, lived eight days, 1 six days, 1 three days, 5 lived over forty-eight hours, 3 lived under twenty-four hours, and 19 under twelve hours." In the present case, so complete was the rally under stimulant treatment that the idea of cardiac rupture, at first enter-

tained, was thought to be beyond the mark, and that the case was, after all, one of temporary cardiac inhibition, from the influence of mental agitation. The sudden death, forty hours later, proved the correctness of the original surmise; whilst the discovery at the post-mortem examination of two distinctly separable layers of clot around the heart demonstrated the fact, that the rent had been temporarily closed after the first occurrence of hæmorrhage. A very important question is here raised; admitting the impossibility of recovery after cardiac rupture, would life have been more prolonged had sedative treatment (as insisted on by writers on the subject) been pursued? This may well be doubted, for although, on *a priori* grounds, it may seem wrong to stimulate to further action the heart so injured, it may equally well be contended that the ventricular contractions would aid in the temporary closure of the rent; whilst on the other hand continuance of the hæmorrhage might be favoured by measures tending to prolong the state of diastolic relaxation. In following the indications for prompt stimulation, as the only measure likely to rescue the patient from imminent death, this line of treatment was deliberately adopted in face of the possibility of such a lesion as actually existed. Had stimulants been withheld the man must have died in the first seizure, and in such a case a respite of a few hours may often be of great moment. The inference is that in similar cases—where diagnosis may be even more certain—the natural indication to administer stimulants may not be so harmful as is generally assumed.

#### RADCLIFFE INFIRMARY, OXFORD.

CASE OF UNUNITED FRACTURE OF THE HUMERUS IN AN OLD MAN SUCCESSFULLY TREATED BY RESECTING THE ENDS OF THE BONES AND FASTENING THEM TOGETHER WITH A PROBE.

(Under the care of Mr. HORATIO P. SYMONDS.)

WILLIAM S—, aged sixty-one, admitted on July 5th, 1882, with an ununited fracture of the left humerus. On March 15th he had been run over by a cart, the wheel of which, passing over his arm, caused a simple fracture of the humerus. It was at once put up by a surgeon in the country with a rectangular and slide splints, and left without being touched for seven weeks. At the end of this time no union having taken place, the splints were readjusted at intervals till his admission.

When admitted there was an oblique fracture about the middle of the shaft of the humerus below the insertion of the deltoid. The fragments were perfectly movable, no callus having been thrown out. The man was in feeble health, appearing prematurely old. The circulation in the extremities was very weak, the hands being always cold and blue. There was no marked rigidity of the arteries, and the urine was free from albumen. The arm was fixed in a plaster-of-Paris apparatus for six weeks. When this was removed the condition was precisely the same as before. The patient complained greatly of the discomfort of the arm, and was willing even to have it removed. Under these circumstances, and notwithstanding the debilitated condition of the patient's health, it was thought advisable to try some operative procedure.

On Aug. 22nd, the following operation was done, with all antiseptic precautions. An incision three inches long was made on the outer side of the arm over the seat of the injury. The ends of the bones were cleared from the surrounding tissues and made to project through the wound. The periosteum was stripped from the ends for about an inch. A small slice of bone was then sawn obliquely off the ends of each, and a hole was drilled through from one to the other. Through this hole a silver-plated steel probe was passed (acting like a hare lip pin), and the ends being drawn together, were fixed by a stout silver wire twisted round the probe in figures of 8. The ends of the wires and the probe were left projecting from one end of the wound, the edges of which were closed by a few silk sutures, and dressed in the usual way. The arm was then fixed by a leather splint, having a steel bar from the elbow to the shoulder in the outer side and an angular splint on the inner side.

The patient went on very well, the temperature only once, four days after the operation, rising above 100°. The arm was dressed at first on alternate days, afterwards at longer intervals. The antiseptics were left off on Sept. 20 and on

Oct. 14 (two months after the operation) the probe was withdrawn without difficulty. It was found that considerable, though not perfect, union had taken place. On admission the arm was quite useless. Now he was able to raise it to a level with the shoulder; he is quite free from pain and has improved in his general health. A small fragment of necrosed bone came away with the probe.

## Medical Societies.

### ROYAL MEDICAL & CHIRURGICAL SOCIETY.

*Spontaneous Postures of the Hand considered as Indications of the Condition of the Brain.—Seventeen Cases of Epilepsy treated with Sodium Nitrite.*

THE ordinary meeting of this Society was held on the 28th ult., J. Marshall, Esq., F.R.S., President, in the chair. In addition to the two papers read and discussed, several specimens illustrative of diseased conditions of the skull, the brain, and its membranes, collected from various hospital museums, were exhibited, as well as an excellent series of photographs from Professor Ziemssen's collection, showing the effect of isolated stimulation of the various facial muscles.

The first paper, entitled "Spontaneous Postures of the Hand considered as Indications of the Condition of the Brain" was communicated by Dr. FRANCIS WARNER. A posture is the relative position of the several members of the body with regard to one another, and the relative position of the individual parts of a member. Every posture is due to a balance of the muscles produced by some portion of the central nerve-mechanism. A weak child spontaneously holds out his hands in the "nervous posture." The limb is now free or disengaged; its posture is the spontaneous outcome of the action of the nerve centres. The wrist is slightly flexed, the metacarpo-phalangeal joints are extended backwards, the internodes being either flexed or straight. This posture is often seen in nervous children; it is usually bilateral. Explanation may be sought after Darwin's method—i.e., observe what advantage attends the posture. The following method appears preferable:—Analysis and analogy show a wrist drooped as in weakness, and the knuckle-joints extended as in conditions of excitability. This posture is sometimes found in spastic contraction. The "energetic hand" may also be a permanent posture resulting from brain disease. The wrist is extended; the small joints are all flexed. This posture is the antithesis of the "nervous hand." The following axiom is assumed:—"If we see some spontaneous nerve-muscular action often repeated in the same and in different subjects, it may be assumed that there is some nerve mechanism corresponding which can act independently." In any particular case the existence of a special centre is strengthened if we can see its action when excited, and again when it is weak. In analysing postures the following "principles" appear useful:—1. The contrast of small parts with large parts. 2. Inter-differentiation—i.e., the relative condition of the large and small joints. 3. Collateral differentiation—i.e., the relative condition of collateral joints. 4. Symmetry or asymmetry in a posture. 5. Excitation of weak centres. 6. General excitement or general weakness; in this case the stronger muscles produce the posture. 7. Antithesis—i.e., the principle that opposite postures may indicate antithetical states of the corresponding nerve-mechanism. 8. Anatomical analysis and description. 9. Analogy between postures. The following suggestions are offered as to determining whether a posture is the outcome of the spontaneous action of the nerve centres: The part must be free or disengaged. Look for analogous postures in brain disease. Look for analogous postures in infants, also in ancient art. Apply the "principles" above given to the case in question. Errors may be made by attributing all postures to the central nerve mechanism. Postures may be due to joint disease, local changes, and organic conditions—e.g., cardiac orthopnoea, the effects of gravity, muscular rigidity, and local injury to nerve. Appendix: A table applying the principles of analysis to eight postures—viz., the nervous hand, the energetic hand, the hand in rest, the straight extended hand, the straight extended hand with thumb drooped, the convulsive hand, the hand in fright, the feeble hand. The paper was illustrated by a large collection of drawings and casts—

THE PRESIDENT pointed out the difficulties that beset so apparently simple a subject, for so many factors were operative in these postures. The author deserved great credit for his painstaking inquiry and analysis of this complex matter.—Dr. HUGHLINGS JACKSON also spoke highly of the author's work, which he characterised as opening up a new subject in practical medicine. Dr. Warner had dealt with one of the most specialised parts, the hand, and it is the hand in all cerebral affections that the more specialised parts suffer in a greater degree than those whose functions are more general. As an instance of the latter, he mentioned the respiratory apparatus, where the same movements are being repeated continuously throughout life. But in the hand we have not only a part which can exhibit a vast variety of movements, but one which has a large number of small muscles carrying little weight; and the more intellectual the actions the lighter are the movements—e.g., the actions of the hand in writing, painting, and drawing, actions which might be contrasted with those of such a muscle as the deltoid, moving the whole limb to bear heavy weights. In a general sense in nervous disease the parts first affected are those of small muscles and small movement. In most cases of epilepsy the fit begins in such parts, so in chorea; so also in the commonest form of progressive muscular atrophy these muscles are the first to suffer. The tremor of paralysis agitans begins in the small muscles. Dr. Warner's work could be more generalised, to include attitudes in disease, as that of paralysis agitans, which is the reverse of the attitude in cerebellar disease; or it may be applied to the face as in the loss of expression seen in double facial paralysis, which gives a sullen look to the patient; in paralysis agitans, where the face is fixed there is a puritanical or aged look. The paper was an inspiring one, and Dr. Jackson regretted that, having no special knowledge on the precise subject, he was unable to discuss it.—Dr. WARNER explained that his object was rather to open up the subject of postures than to give many details, and he had therefore limited the remarks in his paper to two only of the natural postures of the hand. In the Appendix he had applied the same principles to the analysis of eight other postures without exhausting the list. For this study to be clinically useful it was necessary to take special types, from which many variations might arise; and he had taken as types such postures of the hand as had been recorded in works of art for centuries, and which were probably referable to particular conditions of the brain. Trousseau describes the hand in tetany, the fingers flexed over the thumb, and the arching of the metacarpus from its adduction. This arching of the metacarpus is an abnormal condition; another is the drooping of the thumb, which Dr. Warner believed to be the first departure from the normal in the weak hand. The face was even more specialised than the hand as regards its muscularity and movements, and the same principles of analysis might be applied to their study.

A paper was then read, on Seventeen Cases of Epilepsy treated with Sodium Nitrite, by Dr. CHARLES HENRY RALFE. The author, in the first place, claims the credit of first introducing this drug for the treatment of epilepsy to Dr. Law of Hastings, who was the first to administer it, and who has fully described the theoretical reasons which led him to employ it, together with an account of its physiological action in the *Practitioner* for June of the current year. Sodium nitrite in its action resembles nitrite of amyl and nitro-glycerine. It has one advantage over these remedies for the treatment of epilepsy; its effects are produced more slowly and are more permanent in character. The dose, the author's, should just fall short of producing full physiological effect. He advises that care should be taken to ascertain the purity of the drug, as many samples contain an admixture of sodium nitrate. The details of seventeen cases treated by the author in the out-patient department of the London Hospital is then given. Of these seventeen cases, three received no benefit, four improved slightly, one was a doubtful case, whilst nine benefited decidedly. Of all the cases, eight previous to treatment with sodium nitrite had been treated with bromide of potassium. Of these, three (Cases 1, 2, 3) had improved under its use, and went back when the medicine was changed to sodium nitrite. Of the other five, the bromide treatment was inefficacious from the first in three cases; and in two, though it had done good for some time, was losing its effect, and the patients were suffering from bromism. In four of these cases (9, 13, 14, 15) decided improvement followed the change to sodium nitrite, and the other (Case 7) improved to a lesser

degree under its use. Nine of the patients commenced treatment directly with sodium nitrite. Of these, the disease in four was of long standing, and probably the patients had already been subjected to a course of bromide at other hospitals. Of these, two improved under sodium nitrite, and two received decided benefit. The remaining five cases were all tolerably recent ones. Of these, three received decided benefit, one slightly improved, and one was a doubtful case. Among the cases that received decided benefit, the longest exemption from any kind of epileptiform seizure was in Case 17, who went eleven weeks without an attack, four weeks whilst under treatment, and seven weeks after leaving off the medicine. Case 14 went eight weeks without an attack, and had no relapse at the time he was last seen; he is still an out-patient and taking the medicine. Previous to commencing treatment he had on an average three fits a fortnight, and they were increasing. Case 16 remained free for a period of four weeks, and had had no recurrence when he gave up his out-patient letter. Case 9, who had a fit on an average every week, after taking the medicine was free for five weeks. The same result obtained with Case 15, who was free for one month. The author draws the following conclusions from these results:—1. That those cases in which bromide of potassium is of marked service are not generally suitable for a trial of sodium nitrite. 2. That those cases in which bromide of potassium does not agree well from the first will probably be found to improve under sodium nitrite. 3. That to patients who have taken bromide some time, and on whom the drug is apparently losing its effect, or who are suffering from bromism, sodium nitrite is useful as a change medicine. 4. That there is a class of cases, consisting chiefly of minor seizures or convulsive attacks, such as often occur in young persons, usually at night, in which sodium nitrite is especially beneficial.—The PRESIDENT, in inviting discussion, said that in epilepsy so many factors were at work, and the nature of epilepsy was so obscure, that it was difficult to explain the mode of action of drugs upon the disease; but the introduction of drugs was often based upon physiological grounds. Of course many cases of organic disease producing epilepsy were outside the category of remediable cases. He directed attention to a series of preparations collected from the museums of Guy's, University College, and St. George's Hospitals, illustrative of diseases of the cranium and brain producing epilepsy, and expressed the indebtedness of the Society to those gentlemen who had furnished the specimens for exhibition.—Dr. LAW had but little to add to what he had written in the *Practitioner*. He had employed nitrite of sodium in a case upon the theoretical ground that cerebral anemia was one of the factors in producing the fits; and had used the salt in preference to such compounds as nitrite of amyl and nitro-glycerine because of its greater stability. Dr. Richardson in 1865 pointed out the similarity of physiological action of the nitrites of amyl, ethyl, &c., and was inclined to attribute their action to the nitrogen they contained.—Dr. GOWERS after reading Dr. Law's paper had given nitrite of sodium to many patients—about twelve in all and in only one did it appear to do any good. Some of them were patients who had taken bromide for some time without effect; others were cases treated by other drugs. In every case the fits continued, in one or two with temporary cessation which in one case lasted for six weeks, and then the fits returned in spite of an increase of the dose. And very often, the fits cease for a time under any drug that has a considerable action on the system. Even if the theory of the action of the nitrite were correct, and its efficacy proved, he did not think that would establish the fact of cerebral anemia in epilepsy, for flooding the brain with arterial blood would conceivably act beneficially on the nerve tissue without assuming a prior anemia. Nitrite of amyl will check the spasm of tetanus. H. C. Wood of Philadelphia holds it to be more rapid in its action than chloroform in this disease, but no one has ventured to suggest the occurrence of anemia of the spinal cord as the grounds for its use; the condition in tetanus is rather one of hyperemia. Dr. Gowers had also given nitro-glycerine in epilepsy both before and since Dr. Hammond's advocacy of it, but had not found it to have the slightest influence. The dose of nitrite of sodium he had given was ten grains increased to twenty; in one or two cases it had been continued for a period of five months.—Dr. RAMSKILL mentioned the case of a girl five years old who was treated with the nitrite, which was discontinued owing to the great increase in the number of the fits;

bromide was then given with good effect. He had also had several similar cases; but he wished particularly to state his belief that the drug was not without dangerous effect, and referred to three cases in which alarming symptoms were produced by it. Dr. Ralfe's cases were probably chronic ones—e.g., cases of commencing sclerosis, where such treatment might do good; but he did not think it of value in idiopathic epilepsy. He agreed with Dr. Gowers as to any remedy having the effect of temporarily postponing fits, and also that rest alone or change in surroundings will do the same.—Dr. COXWELL gave brief details of three cases in which the nitrite of sodium treatment was compared with valerianate of zinc and bromide of potassium, and in each case fits recurred more frequently under the nitrite.—Dr. HUGHLINGS JACKSON considered Dr. Ralfe's facts too few, and the period of observation too brief, to draw favourable conclusions as to the efficacy of the remedy. He trusted he would pursue his investigations, as any new remedy which can be shown to be a little better than those at present used in epilepsy would be a gain. He would have liked more details as to the age of the patients, and the nature and duration of the attacks. For his own part, he laid great stress upon diet, and was especially careful in restricting nitrogenous food, a fact long ago insisted on by Heberden, and by other physicians, as Troussseau, James Jackson of the United States, Ireland, and West. So far as things go, bromide of potassium was the best; and although Dr. Ringer had demonstrated that potash salts were more depressant than soda salts, yet this was itself an advantage in epilepsy, where it was, above all things, desirable to bring the patient to a "low level." Tonics, as iron, and full diet, were bad. Adverting to the subject of "arresting" a fit, Dr. Jackson expressed his opinion that in the case of epileptiform seizures it was not a good practice to stop the fit—(e.g., by ligature) altogether at its outset, although it might be well to limit it to the limb. The effect of this is to leave the limb more paralysed, but it prevents the fit becoming general, with the resulting loss of consciousness and general powerlessness.—Dr. D. DREWITT drew attention to the method, adopted with good results at the Children's Hospital, of the application of a silk seton in the nape of the neck.—Dr. BROADBENT thought the cases too few and inconclusive to base any precise view of the action of the drug. He was not previously aware that the nitrite of sodium had analogous physiological action to nitro-glycerine; and would rather have thought that the nitrite would take up oxygen and be converted into a nitrate in the economy. He had met with two opposite conditions of the circulation in epilepsy—one of extremely low arterial tension and one of high tension—such vascular condition being probable a consequence and not the cause of the change in the nerve centres. Possibly the nitrite was of advantage in those cases where the arterial tension is low.—Dr. WILKS had not tried the remedy, but agreed with Drs. Gowers and Jackson that any number of remedies will arrest epilepsy, at least for a time. Very slight influences will produce a fit, and very slight influences will arrest it, so that the results are not always to be attributed to the drug that may be given. He instanced a case where a toothache or gum-boil arrested the fits, another where no fits occurred during an attack of erysipelas, and had several cases where epileptics had no fits whilst suffering from fever. In one case of a young lady, who had most severe fits, an attack of small-pox cured her epilepsy without return. He was, therefore, very sceptical as to new remedies in epilepsy, and confirmed Dr. Ramskill's remark upon the influence of rest in hospital in temporarily averting fits. He had often employed setons, and he mentioned one case of a gentleman who had to give up a Government appointment on account of epilepsy, but who had since been free from attacks for eighteen months by wearing a seton.—Dr. BUZZARD asked for information as to the dose, &c., of the bromide in those cases mentioned by the author where that drug had not been efficacious. The susceptibility to bromide varied with the individual; some cases of great severity were controlled by small doses; in other cases the drug had to be pushed to bromism before any effects were produced.—Dr. RALFE, in reply, said that the paper was based on some rough clinical experiments which he had made on hearing from Dr. Law about his case. They were not all chronic cases, most of them being in children. He thought his results had been estimated too highly; for it must be remembered that in only nine out of the seventeen cases did the drug succeed in controlling the fits. To those

who had been long taking bromide without benefit the bromide had been given in various doses. He thought a good deal depended upon the purity of the nitrite and the strength of the dose. He had found large doses to have no effect, and it was only after gradually trying smaller doses that he at length arrived at a dose of about twelve grains as the most suitable. Since the paper was written he had on one day prescribed the nitrite to three patients, two being cases of epilepsy, and one of asthma. All of these patients returned to the hospital suffering from the toxic effects with cyanotic symptoms. The sample of nitrite given to these patients was different from that previously described, and it had been set aside for analysis. It showed, however, that samples of the salt vary, and also that it was important to ascertain the physiological dose of each individual. He had also found marked differences as to their efficacy in epilepsy in two other samples, and suggested that possibly the negative results obtained by Drs. Gowers and Ramskill might depend on such differences.

The PRESIDENT directed attention to a series of photographs lent by Dr. Ziemssen, of Munich, showing the effect of stimulating the facial muscles separately, and interesting as an analysis of facial expression.

### CLINICAL SOCIETY OF LONDON.

*Symmetrical Congestive Mottling of the Skin.—Lumbar Nephrectomy for Carcinoma.—Subcutaneous Rheumatismal Nodes.*

THE ordinary meeting of this Society was held on Nov. 24th, J. Lister, Esq., F.R.S., President, in the chair. The proceedings were interesting, especial attention being given to the subject of renal surgery, arising out of a case communicated by Mr. J. Adams; subcutaneous rheumatic nodes were well shown in two cases contributed by Dr. Duckworth, who read a paper on them; whilst Dr. Cavafoy detailed the particulars of a peculiar cutaneous mottling, of which he showed two examples. Mr. Howard Marsh exhibited a child with very extreme deformity of the skeleton from rickets.

Dr. CAVAFY read a paper on Symmetrical Congestive Mottling of the Skin. In this paper two cases of a curious affection of the bloodvessels of the skin are described. The first was a young woman, aged twenty-two, shown to the Society, who was first seen in March, 1882, when the condition had existed for three years. It began as a reddish mottling of the left shoulder, which gradually spread down the arm, and soon afterwards appeared on the right arm, the cheeks, and both thighs, gradually increasing in intensity. At the date of her first visit the skin of both cheeks was mottled with blotches and irregular rings and streaks of a bluish-red colour, most marked on the right side, not prominent, and covered by normal epidermis. Singular, dull, bluish-red maculæ and irregularly confluent blotches and streaks forming reticulated annular and gyrate figures occupied the exterior surfaces of both arms and forearms and the backs of the hands, being especially distinct over the left wrist. The front and outer surface of both thighs near the knees was similarly mottled, but in a much less degree. The blotches and streaks were not sharply circumscribed, and disappeared completely on pressure, leaving in some spots a delicate fawn-coloured pigmentation. The marking also disappeared from the arms when they were held up, and returned when they were allowed to hang down. The neighbouring skin was normal in all respects, and the general health perfectly good. The girl had rheumatic fever a year before the mottling commenced, but the heart was unaffected. The only departure from perfect health was a liability to "dead fingers" and occasional dyspepsia. She continued to attend for a month, with no change in the state of the skin. The markings were always intensified by cold; they never completely disappeared, and were throughout unaccompanied by pain, numbness, tingling, or any abnormal sensation. She is still in the same condition. The second patient, also shown to the Society, is a healthy young woman, aged twenty-one, who has been under observation since August, and in whom the affection has existed eighteen months. It began over the ankles, and gradually spread to the legs and thighs. Twelve months later the arms became affected, and quite recently blotching has begun on the waist; the face has remained free. The mottling is an almost exact counterpart of that in the first case; but more

ensive and of a deeper bluish-red colour over both legs at the front of the thighs, especially near the knees. It is limited on the exterior surfaces chiefly, but also extends chiefly over the flexor sides. The condition above described was only due to venous stasis or passive congestion of the skin, and appears to be an exaggeration of the marbling often seen on the skins of children and young persons after exposure to cold; but in the above cases, though cold intensifies the marbling, the congestion remains more or less evident at all times. It is probably due to a vaso-motor neurosis, but the share taken in its production by arteries and veins is not easy to apportion. The affection appears to be quite harmless, and has not led to any changes except pigmentation, and that only slightly; but the disfigurement, especially when the face is attacked, is considerable. The treatment employed has not influenced the condition in any way.—Mr. S. MACKENZIE said the cases were interesting and rare, such a condition seldom being so marked and permanent; and Dr. Cavañy's explanation of it was probably correct. The cases had a superficial resemblance to similar conditions due to direct exposure to heat, as from much tanning before a fire. A condition of vaso-motor neurosis of the extremities has been described by Weir Mitchell, of which Dr. Mackenzie had seen one case; but this differs materially from these present cases.—Dr. GLOVER asked if the effect of a bandage had been tried. He was much struck by the good effect of such a measure in a case of long-standing purpura of the legs, where the application of an elastic stocking resulted in a cure.—The PRESIDENT alluded to the symmetrical character of the mottling proving it to be due to a neurotic origin.—Dr. CAVAÑY, in reply, said that the pigmentation, due to exposure to a fire, was excluded by the fact that the colour could be pressed out of the part, and that neither patient had been so exposed; further, the mottling in the present cases is diminished by heat. The vaso-motor neurosis of Weir Mitchell, of which a case was brought before this Society by Dr. A. Sturge, is different. The closest alliance was, perhaps, to local asphyxia, which may lead to symmetrical gangrene (Reynaud). The present cases might be a minor degree of that condition. Dr. Glover's suggestion was only applicable to the extremities.

Mr. JAS. E. ADAMS read notes of a case of Lumbar Nephrectomy for Carcinoma. The patient, a male, aged thirty-nine, had intermittent hæmaturia for two years; pain in right loin; latterly profuse hemorrhage from the kidney, leading to marked anaemia; blood, pus, triple phosphates, and epithelium in urine. The disease was clearly located in the right kidney, but its exact nature was not certain. The operation was undertaken in order to explore, and, if necessary, to remove the right kidney. By an incision parallel with the lower border of the last rib, the kidney was easily explored, and found to be the seat of a new growth, which had increased its size to about double the normal. In order to extract the organ it was necessary to enlarge the incision upwards; the organ was adherent to the peritoneum, and in separating it the serous cavity was opened. Owing to the size of the tumour, the ureter and vessels could not be tied separately, but were encircled *en masse* by a whipcord ligature. The peritoneal wound was closed with a catgut suture; the skin wound was freely drained. The hæmaturia ceased at once. The wound healed in a few weeks; but the patient gained no strength, suffered much throughout from cough, and was transferred back to the care of the physician, and died forty-four days after the operation, with effusion into both pleuræ, plugging of the left renal vein, and numerous secondary deposits in the lumbar glands and on the ribs.—Mr. CLEMENT LUCAS congratulated Mr. Adams on the success of the nephrectomy; though unfortunately the disease was too advanced for complete eradication. He had twice explored the kidney this year. In one case there were typical symptoms of stone; although the man had a severe rigor before passing the blood, which was attributed to his being moved. Mr. Lucas cut down on the kidney and punctured it in as many as five or six places for the depth of an inch and a half; no bleeding occurred, but the kidney appeared to be puckered. It was probably a strumous kidney. He mentioned these cases in order to encourage physicians to explore the kidney more readily in doubtful cases. No disturbance arose from the exploration, and the wounds healed rapidly and painlessly. The operation, then, might be regarded as perfectly safe, with no more danger than an incision of similar length in the calf of the leg.—

Mr. GOLDING BIRD asked Mr. Adams whether the opening was enlarged in a vertical or horizontal direction.—Dr. FOWLER had lately had a case under his care with symptoms of renal calculus in which Mr. Morris explored the kidney, punctured it in several places, without finding a stone, and the wound healed perfectly.—Dr. DOUGLAS POWELL asked for the results of cases where the operation is completed and the stone removed, but his impression was that many cases were disastrous in their results. He thought that we should not consider too much the fact that the kidney had been explored without finding a stone without ill results. These cases of stone in the kidney often go on for many years, and eventually the stone is discharged from the bladder. Therefore he did not think nephrotomy an operation of necessity or always justifiable. It would be a matter of importance as a guide to its performance if a diagnosis could be made as to the size of a stone. A small stone will give rise to as severe symptoms as a large one; and he cited a case where a small stone was eventually passed, but the patient returning later with renal symptoms, an exploratory incision was made, and no stone was to be found.—Mr. BARKER said that for the very reason urged by Dr. Powell the kidney ought to be explored. A stronger reason still for calling in the aid of the surgeon is that these operations can be done without any risk. He alluded to a case in which all the symptoms of stone occurred in a child; he explored and punctured the kidney without finding a stone. The wound healed rapidly. If all the cases of exploration were recorded it would encourage the routine resort to the procedure. The point between nephrotomy and nephrectomy turns upon the extent of disorganisation of the renal tissue. A small stone may be removed from the kidney without any risk whatever; but the case is altered when much disorganisation of the kidney is present.—Dr. WILBERFORCE SMITH alluded to one point in the diagnosis of stone in the kidney—viz., that of treatment by copious water-drinking, so as to produce diuresis. It was his habit to tell the patient to keep his urine down to a low specific gravity. There is prompt and considerable relief; the hæmaturia ceases and the pain is modified.—Mr. HAWARD, recurring to Mr. Adams's paper, asked as to the diagnosis between stone and malignant disease. There was considerable enlargement of the kidney; but was the examination made under an anæsthetic? In that way a stone may be felt in the kidney. Mr. Haward had succeeded in palpating an enlarged kidney by this manner in a case related last year. He also asked whether Mr. Adams had noticed great frequency of micturition, for a stone in the kidney is often accompanied by an irritable bladder, as Sir B. Brodie long ago pointed out.—Mr. H. MARSH, in reference to the question of making out a large kidney under an anæsthetic, said that in a case he related last year, no one succeeded in palpating the organ; but when he came to operate it was found to be very large indeed.—Mr. ADAMS, in reply, said that he enlarged the opening in a vertical direction, almost at right angles to the first incision. If he were sure that the kidney was very large and occupied by a large growth, the abdominal section would be preferred. He did not think that Dr. Powell's application of the term "disastrous" to exploration of the kidney was justifiable; and the operation is not performed except the patient is in much suffering and unable to perform his duties. He was in favour even of leaving a stone in the bladder if there was no suffering. The decision to remove a kidney would be based on the condition of the organ. This patient was examined thoroughly under an anæsthetic; but the difficulty or ease of the diagnosis will depend greatly on the amount of subcutaneous fat in the individual.

Dr. DYCE DUCKWORTH read notes of two cases of Subcutaneous Rheumatismal Nodes. Case 1. S. C.—, aged twenty-four, domestic servant, came to St. Bartholomew's Hospital on account of painful swelling on the right hand and knee. She had had no serious illness, no rheumatic fever or chorea. Suffered for eight years past with pains in the joints and limbs. Crackling in the larger joints was noticed. The nodules began eight months previously on the right hand, elbow, and knee, and are found to be quite subcutaneous, painful on pressure, and attached for the most part to sheaths of the tendons or deep fasciæ. The fingers were knotty at the joints and the right little finger was turned outwards at the last phalanx (not as the result of injury). The first sound of the heart was found roughened and somewhat reduplicated. The urine was alleged to be occasionally thick. The patient was exhibited, and casts of the right

hand and knee were also shown. In three months' time it was found that some of the nodules had grown larger and that new ones had appeared. Signs of slight hypertrophy of the left ventricle of the heart were noted, and the first sound was rough and reduplicated at the apex. Treatment by cod-liver oil and iodide of iron and potassium had not proved of material service, and there were still articular pains. The nodules ached more in damp weather. Case 2. E. L.—, aged nine years, a school girl, had suffered from pains in the feet, knees, and arms for two months, and at that time nodules were first seen on the ankles, elbows, and knees. The legs and hands were also swollen "as if dropsical." There was no history of chorea. Nodules of various sizes were found on the sheath of an extensive tendon on the metacarpus, on the olecranon, on the spine of a dorsal vertebra, on both patellæ, and on an external malleolus. The nose and finger-ends were clubbed. The cardiac physical signs indicated mitral regurgitation. In three weeks the nodules on the patellæ appeared larger. The child ceased attendance, and its parents could not be traced subsequently. A cast of one knee was taken at the first visit. Both cases were well-marked examples of rheumatismal subcutaneous nodules. Both occurred in females, as is found to be the case in most instances. The nodules have persisted longer in the first case than has hitherto been previously noticed—fourteen months against five,—and the age of this patient is more advanced than in most cases recorded. The heart was affected in both patients. All the points noted supported the previous observations of Drs. Barlow and Warner, as communicated last year to the International Medical Congress.—The PRESIDENT said it was remarkable that a disease like this should only be recently recognised. He was struck with the fact that the heart should be affected in these essentially chronic cases; was it a general observation that endocarditis accompanied these manifestations?—Dr. GREEN had seen one case in a boy, sixteen years of age, with acute rheumatism; the nodules were very marked. They were not complained of, but discovered accidentally. The heart disease seemed to develop during the development of the nodule.—Dr. BARLOW did not think there was always heart disease in association with these nodules, for some were cases allied to rheumatoid arthritis. But when one finds these nodules one should be on the *qui vive* for heart disease. About a year ago a young man came to the hospital with nodules about the patellæ and elbows. He had been in hospital four months before with subacute rheumatism, but no heart disease. Dr. Barlow sent him home, and, although the temperature did not rise above normal, prescribed salicylate of soda. A mitral murmur developed, so he could say these nodules make one look out for a form of rheumatism apt to attack the heart. The view put forward by himself and Dr. Warner was that these nodules were outgrowths of fibrous tissue, analogous to the simple vegetations found on cardiac valves—i.e., the slow change in the mitral valve which may protect the valve without causing any fibrinous deposit upon it.—Mr. GODLEE asked what structure was affected by these rheumatic nodules, for in a case supposed to be ganglion on the palm of the hand there were nodules on the palmar fasciæ. On searching he found many nodules elsewhere, and detected a bruit at the heart.—Dr. BARLOW had satisfied himself that these nodules were attached to the deep fasciæ. It had been asserted that the periosteum was their seat; but this is not the case; it is the deep fascia, and often the tendons.—Mr. BARKER believed he had seen these nodes in a middle-aged woman, between forty and fifty, suffering from rheumatic arthritis.—Mr. TRAVERS mentioned a case in a patient forty-five years old. It was a severe attack of acute rheumatism, with high temperature. The nodules which appeared on the right elbow and the patella caused some pain; there was no cardiac disease. The nodules eventually disappeared. This case was not benefited by salicin.—Mr. GOLDING BIRD asked whether the nodules were allied to Dupuytren's contraction of the fingers. Some years ago he saw a case of this affection in an early stage in a woman of forty-five; there were nodules on the palmar fasciæ adherent to the skin and tendons. No rheumatic pains. Observed for some months, the nodules gradually diminished under iodide of potassium. They had since recurred. The fingers were not much bent, and under treatment could be straightened.—Dr. DUCKWORTH, in reply, took the opportunity of stating that English literature was much indebted to Dr. Barlow and Dr. Warner for their papers on this subject at the Congress last year. He believed Mr. Parker had examined

these nodules microscopically, and found them to consist of delicate fibroid tissue. They come and go quickly, lasting in one of his cases for six months, the longest recorded. As to age, the majority of cases are in young people, but he had seen cases in old people.

### OBSTETRICAL SOCIETY OF LONDON.

A MEETING of this Society was held on Wednesday, Nov. 1st, 1882, Dr. J. Matthews Duncan, President, in the chair.

*Interstitial or Tubo-uterine Gestation.*—Mr. ALBAN DORAN exhibited a specimen of this condition. The gestation cyst was situated at the right side of the fundus uteri. At the anterior and outer aspect of the cyst the round ligament sprang from it, and the Fallopian tube passed into it, expanding as it did so into a funnel-shaped orifice. At the opposite aspect the cyst bulged into the uterine cavity, and a bristle could be passed from the uterus through the tube into the cyst; the tube being here also dilated into a funnel shape at its entrance into the cyst. The tubal origin of the cyst was thus proved. It had burst at the second month. There was a corpus luteum in the right ovary. Mr. Doran had examined other cases of the kind in the London museums, and gave an account of them. He remarked on the rarity of the condition, and the tendency to early rupture. Had the abdomen been opened, amputation of the uterus would have been the only practicable treatment. He thought that cases in which development in a supposed hernial pouch of the uterus was suspected were probably tubo-uterine.

*Cephalotribe.*—Mr. C. E. JENNINGS exhibited an improved cephalotribe.

*Hermaphrodite.*—Dr. CHALMERS exhibited the genito-urinary organs of a child in which the internal parts were female, while the external resembled those of the male. The clitoris was grooved below, but not channelled.—Mr. DORAN said that grooving, and even channeling, of the clitoris was normal in some of the lower animals.—Dr. FANCOURT BARNES informed the Society that the child he had exhibited at the last meeting had since died, and proved to be a female.—Dr. CHAMPNEYS exhibited the genito-urinary organs of a female with extroversion of bladder, described by him in the St. Bartholomew's Hospital Reports. The external genitals were such as might belong to either sex.

*Torsion of Cord.*—Dr. CHALMERS also showed an Umbilical Cord presenting remarkable twisting and narrowing near the umbilicus.

*Tumour of Placenta.*—Dr. GALABIN showed (for Dr. J. C. ROBERTS) a placenta in which was embedded a tumour about the size and shape of an adult human heart. It was encapsuled, and on the uterine side covered by a complete layer of placental tissue. Near it were several small similar detached masses.

*Description of a Kyphotic Pelvis, with Remarks on Breisky's Description.*—This paper, by Dr. CHAMPNEYS, was read. The pelvis, except for slight asymmetry, and a process which the author termed "posterior spondylolisthesis," was a typical kyphotic pelvis. The author criticised Breisky's description, laying stress on the influence of sitting, which, in the kyphotic pelvis, he believed, increased the inversion of the tubera ischii, while in the flat pelvis it increased their eversion; the difference depending upon whether the deformity caused the tubera ischii to be inside or outside the line transmitting the body weight—i.e., the sacro-iliac synchondrosia.

*Puerperal Diabetes.*—A paper on this subject by Dr. MATTHEWS DUNCAN was read. The author pointed out the distinction between the slight glycosuria of pregnant and suckling women and real diabetes, with its polyuria and large amounts of sugar. Physicians and surgeons were well aware of the dangers introduced into their cases by complication with diabetes. But the subject of diabetes complicating pregnancy and parturition had attracted almost no attention, and this probably arose from its rarity, which might be accounted for by the disease frequently destroying in women the sexual energies, as it is said to do in man. The author had collected twenty-two cases in fifteen women, and they demonstrated the great gravity of the complication, as respects both mother and child. Of the twenty-two pregnancies (including those ending prematurely), four had a fatal result soon after delivery. In

seven of nineteen pregnancies in fourteen women the child, after reaching a viable age, died during pregnancy. In two the child was born feeble, and died in a few hours, making an unsuccessful issue in nine of nineteen pregnancies. The histories showed that diabetes may intervene on pregnancy; that it may occur only during pregnancy, being absent at other times; that it may cease with the cessation of pregnancy; that it may come on after parturition; that it may not come on in a pregnancy occurring after its cure. They showed that pregnancy may occur in a diabetic woman; that it may be not appreciably affected in its natural progress and termination by the disease; that it is very liable to be interrupted by death of the fetus.—Dr. JOHN WILLIAMS thought that these cases were less infrequent than, owing to the fact that the urine was not always examined, was supposed. He had met with four. A trace of sugar in the urine was common, but this was not diabetes.—Dr. ROBERT BARNES had investigated the condition of the urine in pregnancy as to albumen, urea, and sugar. The occurrence of sugar was physiological, though not constant. Sinéty had shown that sugar appeared in the urine when lactation was suppressed; this was of interest in connexion with the normal fatty change in the liver shown by Tarnier to occur in pregnancy. He (Dr. Barnes) drew a parallel between albuminuria and glycosuria during pregnancy. Both were physiological, but might pass the physiological boundary, and then grave accidents ensued.—Dr. CHAMPNEYS inquired as to the treatment.—Dr. CARTER said that the tendency of diabetics to collapse and coma would make us expect danger from pregnancy and labour.—The PRESIDENT said that the terribly fatal complication he had been describing had no relation to normal glycosuria. He thought, with Dr. Williams, that attention having been drawn to the subject, more cases would be published. He could lay down no special rules as to treatment.

*On the Treatment of Post-partum Hemorrhage by Hypodermic Injections of Ergotinine.*—A paper on this subject, by Dr. C. CHAHBAZIAN (Paris) was read. Ergotinine was the alkaloid of ergot of rye; insoluble in water, soluble in alcohol or chloroform. One pound of powdered ergot yielded three grains of ergotinine. It was indicated in post-partum hæmorrhage due to imperfect contraction of the uterus. The dose for hypodermic injection was five to ten minims of a solution containing one-fiftieth of a grain in twenty minims. This might be repeated if necessary, but more than twenty minims should not be given. This produced strong and permanent contraction of the uterus, acted more quickly than ergotine (which was only an extract of ergot), and did not cause local abscesses or indurations. Ergotinine was to be used as morphia to extract of opium. It was discovered and prepared by Tanret of Paris.—Dr. CHAMPNEYS inquired how long ergotinine would keep.—Dr. WILTSHIRE suggested that the hypodermic injection of ether might with advantage be combined with that of ergotinine.—Dr. BRUNTON asked how long ergotinine took to act.—Dr. CHAHBAZIAN said that uterine contraction usually came on in from two to five minutes after the injection of ergotinine. He could not say how long ergotinine would keep.

## Reviews and Notices of Books.

*Chapters in the History of the Insane in the British Isles.* By D. HACK TUKE, M.D., F.R.C.P. London: Kegan Paul, Trench, and Co.

DR. HACK TUKE'S work is an addition to the literature of insanity that was greatly needed; it has been executed at the right time, and the author is in every way qualified for the work he has undertaken. His book manifests a wide and liberal comprehension of this subject; bears evidence of a most intimate and thorough knowledge of all relating thereto; and shows a most laborious, exhaustive, and painstaking power of research, together with an impartiality and freedom from prejudice, most remarkable in one so intimately connected with and so deeply interested in his subject. The wish might perhaps be expressed that Dr. Tuke had not been so simply historic, but had at times appended his own conclusions in regard to the opposing opinions so clearly and fairly stated. In manner the facts are well put

and interestingly associated. The book will not only be a medical classic, but will be read with interest by laymen, and may thus greatly aid in dispelling the ignorance that exists in the public mind in regard to asylums and the treatment of the insane.

The early chapters trace the popular idea of insanity, from the belief in demoniacal possession prevalent in early Saxon times, to the later beliefs in witchcraft and peccant humours in the blood. Side by side with this, the treatment is given, often amusing, in the mixture of exorcism, of superstitious spells, and of emetics and purgatives, with flagellation.

The history of Bethlem and St. Luke's displays a great amount of interesting antiquarian research, and affords an opportunity for the comparison of the former and present treatment of the insane by the introduction of plates representing a ward in Bethlem in 1745 and one at the present day, the details of which are more convincing than any words could be. A sketch of the miserable state of lunatic asylums in England, emphasised by the unfavourable comparison made by John Howard between St. Luke's and an asylum in Constantinople, is followed by the history of the foundation of the York Retreat in 1792 by William Tuke, the grandfather of the author. The principles for the moral treatment of the insane, laid down by this noble man, and quoted here, must ever remain as fundamental truths.

The history of the legislation for lunatics is next carefully traced, with the date of establishment and cost of the various principal asylums, acknowledgment being made of the great share taken in this work by the present chairman of the Lunacy Commission, Lord Shaftesbury.

In the next chapter the development of the non-restraint system is shown. The first efforts were made at the Lincoln Asylum by Dr. Charlesworth from 1819 to 1835, and from that date to 1839 by Mr. Gardiner Hill, who was the first to assert the principle of the entire abolition of mechanical restraint. Drawbacks in the shape of broken ribs, &c., at the Lincoln Asylum, as Dr. Tuke points out, might have produced a reaction but for Dr. Conolly's success at Hanwell, leading to the almost universal adoption of the principle in Great Britain. The disadvantage of large asylums in the loss of "individual and responsible supervision" is quoted from the Report of the Commissioners in Lunacy for 1857; regret must be expressed that this principle has been so much lost sight of in later years. The assertion made in the same report that large asylums are more costly than small is refuted by statistics, in an appendix. It should be remembered, however, that an economy may be apparent only.

Chancery Lunatics form the subject of another chapter, in which Dr. Lockhart Robertson's comparison of the 34.6 per cent. of those patients treated in private houses with the 6 per cent. of private patients so treated under the Lunacy Commissioners is reproduced.

In the chapter on Idiots and Imbeciles attention is drawn to the fact that accommodation for the teaching and training of this class in England is only provided for 1147, or 3 per cent. of the estimated total in the population. Dr. Tuke advises the establishment of additional training institutions, and quotes the conclusions of the Charity Organisation Society on this subject.

The history of the insane in Scotland is given in a very interesting form. It is noteworthy that so early as 1838, in some Scotch asylums amusements and employment were very fully carried out, while in 1855 the condition of the insane in many others was of a deplorable character. The points of treatment coming into vogue in Scotch asylums are also dwelt upon, such as the abolition of airing the open door system, and liberty on parole.

In Ireland, so late as 1815, it was reported to a special

commission "that when a strong peasant becomes insane the only way they have to manage is by making a hole in the floor of the cabin, not high enough for the person to stand up in, with a crib over it to prevent his getting up." Dr. Tuke traces, with his usual care, the legislation by which this condition of things has been amended.

The book concludes with the interesting address on the progress of psychological medicine during the last forty years, delivered by Dr. Tuke to the Psychological Association in 1881.

No one can arise from the perusal of this work without feeling an increased interest in the advancement of the humane treatment of the insane; and the hope may be expressed that this book may exercise an important influence in preventing the principle of "personal treatment," advocated by his illustrious ancestor, from being overlooked or ignored, in the tendency to excessive size in asylums, which an erroneous idea of economy is now developing.

*Die Öffentliche Reconvallescentenpflege.* Von Dr. PAUL GUETERBOCK. Leipzig: F. C. Vogel. 1882.

THIS work relates to the treatment and management of convalescents in homes and in hospitals. All points connected with this subject are discussed fully in every detail, so as to make the volume extremely valuable for purposes of reference. The first portion of the work especially aims at establishing beyond all question the necessity for the existence of convalescent institutions, and the importance of treating convalescents from a public health point of view. After considering most of the details connected with their situation, construction, and management, the author gives a plan and account of the asylum at Vincennes, and another of Burdett's "Convalescent Cottage Hospital." He takes these two as typical examples of what convalescent hospitals should be, although they are constructed on different principles. The vexed question of day rooms is fully gone into, and although Dr. Gueterbock approves of them as a whole, still he recognises Miss Nightingale's objection as to the difficulty of preserving discipline in them. He insists that patients recovering from chronic maladies should be just as much entitled to admission as those after acute diseases, and also that the treatment of convalescents should not be considered purely as a matter of charity. The second part of the volume is devoted to the special consideration of the working of the system in those European countries where it may be regarded as having taken firm root—namely, in Germany, England, and France, brief mention also being made of Italy, the Netherlands, and United States of America. It is flattering to read page after page of testimony to the efficiency and excellence of the English establishments. The boarding-out system is also highly extolled; although the author wisely remarks on the necessity of a very careful choice of boarders, not so much on account of their special ailments as of their moral character and social condition; in his opinion it is especially of advantage in chronic cases. Dr. Gueterbock, however, has apparently not become acquainted with the excellent results of the system obtained in connexion with the Cork Union, which were published not long ago in THE LANCET. In conclusion, the volume dwells upon the position of Germany as regards public convalescence; and the author deploras the backwardness of his own country and the lack of interest taken in the question by its people. We can cordially recommend Dr. Gueterbock's book; it is sound, practical, and thoroughly trustworthy, and fully maintains the credit the German school has obtained for producing works of solid information based on industrious research and high scholarship.

*The Journal of Anatomy and Physiology.* Conducted by Professors G. M. HUMPHRY, WM. TURNER, and J. G. MCKENDRICK. Vol. XVII., Part 1. October, 1882. London: Macmillan and Co.

THIS number contains eleven articles, namely:—1. The Lymphatics of the Walls of the Larger Bloodvessels and Lymphatics, by George and Elizabeth Hoggan. 2. Micrococcus Poisoning, by Alex. Ogston. 3. Omphalo-Mesenteric Remains in Mammals, by Dr. W. Allen. 4. The Action of Saline Cathartics, by Matthew Hay. 5. A hitherto undescribed Fracture of the Astragalus, by Francis Shepherd. 6. A Secondary Astragalus in the Human Foot, by William Turner. 7. Note on the Rectus Abdominis et Sternalis Muscle, by G. E. Dobson. 8. Ectopia Vesicæ, and other Imperfections of Development in a New-born Infant, by Francis Ogston. 9. Nickel and Cobalt, their Physiological Action on the Animal Organism, by Dr. Anderson Stuart. 10. A Kerato-thyro-hyoid Muscle as a Variation in Human Anatomy, by S. G. Shattock. 11. Cessalpino and Harvey, by Professor Humphry.

## Analytical Records.

### SNOW'S CARBOLISED EAU-DE-COLOGNE AND LAVENDER-WATER.

(R. SNOW & CO., SHAFTSBURY-ROAD, LONDON, W.)

It is curious how little the carbolic acid in these preparations interferes with the delicate perfumes with which it is mixed. It can just be perceived, and that is all; and yet it exercises a marked disinfectant action on the air of a sick-room.

### VASCON. (SPANISH RED WINE.)

(GRITTEN & POOLEY, CHAPEL-PLACE, OXFORD-STREET.)

Several good Spanish wines of the Bordeaux or Burgundy type have lately come before us. Vascon is a wine of the same class. It is a genuine, sound, and somewhat full-bodied wine, decidedly superior, in our opinion, to most if not all French wines sold at the same price. It is evident that for ordinary unfortified table wines we need no longer depend entirely on France and Germany.

### WHEELER'S EMULSIO PICIS LIQUIDÆ.

This is a brown viscid fluid, representing, in a convenient form, the constituents of wood tar. Of the value of tar as a medicinal agent there can be no question. As an external application it is largely employed in many forms of skin disease, especially the scaly varieties; whilst internally it is used with advantage in the treatment of chronic bronchitis and other affections of the mucous membranes. For the preparation of tar-water, it is recommended that the emulsion should be diluted with forty parts of water, and the mixture filtered. As a disinfectant a somewhat weaker solution would suffice.

### ADEPSINE (PURE WHITE AND ORANGE-YELLOW).

Prepared under the direction of Prof. Dr. R. Fresenius.

(WILLERINGHAUS, KLINKER, & CO., HAMSELL-ST., LONDON, E.C.)

This is a petroleum product sold in several forms—white and yellow, solid and liquid. The liquid oil is a remarkable substance. It is rather more limpid than olive oil, is perfectly free from taste and smell, and is so stable that it is hardly attacked by sulphuric acid, caustic soda, or metallic sodium. Such an oil cannot become rancid, and is admirably adapted for surgical use. White adepsine is really absolutely white, and, like the liquid, is perfectly free from taste and smell. It is of about the consistence of ordinary lip-salve, and is an excellent ointment for the skin.

# THE LANCET.

LONDON: SATURDAY, DECEMBER 2, 1882.

THE actual value of new discoveries in science can never be at once appraised. It is long before the true relations of fresh facts can be ascertained. They are magnified by the halo of novelty which surrounds them, and which itself depends on the mists of ignorance that prevent us from estimating the proportions, and discerning the position, of a new light in the sky of science. Sometimes a discovery at first is undervalued. Modest and unobtrusive in appearance, its significance is only realised when long-continued observation has shown its true position, or revealed the order to which it is the key. Much more frequently the influence of a new discovery is over estimated. Expectation is aroused by the trumpet-blasts which herald its approach, and the discovery is received with universal acclamation, as explaining all things, or about to explain them—as effecting all things, or about to effect them. This is rarely the fault of the discoverers themselves. New facts are never brought to light but after long and patient search, and he who is most familiar with the region in which the discovery is made is least likely to exaggerate the value of the fresh-found truth. Of no advance in medical science is this more probably true than of the wave of discovery on the crest of which pathologists now find themselves. Far be it from us to undervalue the remarkable facts of the relation of living organisms to disease, which have been ascertained by the not less remarkable investigations of the recent years. Their profound importance is beyond all question, and they will certainly constitute a chief landmark of the progress of medical science in the present century. But in the profession, and even more outside it, there has been, and still is, a widespread expectation of practical results of the highest importance from these discoveries—an expectation of an immediate and vast increase in our power of dealing with disease, of preventing its occurrence, and of curing it when it has developed. A caution is needed against such exaggerated expectation. That “knowledge is power” is not, alas! an aphorism of universal application. Doubtless, no great advance in our knowledge of disease can ever occur without entailing some increase in our power of coping with it, but every consequence does not closely follow its cause, and though knowledge comes, wisdom, its practical application, lingers on the way. It may be doubted whether there is at present any satisfactory evidence that these discoveries have yielded the slightest increased power of dealing with the diseases of mankind. Most, if not all, the means of treatment and of prevention, which they suggest, have been in use before, and if they have suggested some new methods, the value of these has not yet been proved by practical results. The discoveries enable us to understand the *modus operandi* of certain influences, morbid and therapeutic, more clearly than before, but there are others on which these new facts do not at present throw the faintest light.

We may take as an instance the remarkable discoveries regarding the relation of bacteria to tuberculosis. These have been at once received as evidence of the contagiousness of phthisis. All that they really do is to enable us to understand how phthisis may be contagious. They afford no proof that it is, and at present there is no more evidence of its contagious character than there was before. Rare instances of its apparent communication from one person to another have long been recorded, and before the discovery of the organisms there was some evidence—not very strong, however—to show that the disease may be produced by the consumption of the flesh of diseased animals, and still slighter evidence that it may be contracted from milk. But this is all. Indeed, so far as the indirect influence of the discovery can be traced, it has rather increased the evidence to show that the disease is not contagious, for it has led to the collection of facts, such as those lately published by Dr. THEODORE WILLIAMS, which prove that the conditions of aggregation, which conduce most powerfully to the extension of really contagious diseases from the sick to the well, are without influence in the case of phthisis. On the other hand, the discovery of the bacteria has increased the difficulty of explaining the influence of heredity, and still more the influence of subsoil drainage on the occurrence of the disease, so ably worked out by Dr. BUCHANAN. It has led to the adoption of antiseptic expedients in the treatment of phthisis, to the suggestion of numerous inhalers and inhalations but there is at present no evidence of their specific utility to the patients, although there is considerable evidence that they are of practical value as a means of displaying the names of physicians on the counters of chemists.

The discoveries and inferences regarding the relation of organisms to acute specific diseases force the same conclusions upon us, and also upon others, if we may judge from the cautious utterance upon the subject which Prof. JACCOUD lately delivered, in a lecture inaugural to his course of medicine at Paris. The question of the origin, prevention, and treatment of the acute specific diseases of man remains exactly as before the discovery of the relation of special organisms to some of them. Very wisely does Prof. JACCOUD warn his hearers against the “exclusivism” which would regard the bacteria as all and everything in the pathology of disease. He reminds us that the liquids in which bacteria grow have been proved to have toxic properties apart from the formed organisms, and that even the right to accuse bacteria of being the infective agents where they have been found, does not give us the right to accuse them where they have not been found. It is still unproved whether the different bacteria are of specific nature, or whether they acquire specificity under certain conditions of development. “Knowing,” he concludes, “the influence of the infected bacteria, we know one of the agents—say, if you will, the most powerful agent—in the diffusion and conservation of infectious diseases; but this conception still leaves us as ignorant of the morbid poison itself, leaves us as powerless in direct prophylaxis, as we were when we spoke of miasma instead of bacteria. Now, as then, we can only learn the real causes of these diseases by ascertaining the conditions in which the infective agents, judged by their effects, arise; by ascertaining the circumstances which limit or facilitate their diffusion; and by ascer-

taining what conditions, cosmical and personal, are opportune for their development."

THERE can be no doubt of the vast importance of, as well as the necessity for, the effectual practical teaching of Midwifery in our medical schools. The great majority of all those who engage in the private practice of medicine are called upon to attend women during their lying-in. A very large proportion of women who suffer from diseases peculiar to their sex refer their suffering to a previous labour, and justly. It has been proved that the mortality in childbed is very great—about 1 in 120; and in all cases of difficult labour two lives, that of the child and that of the mother, are at stake. These facts sufficiently testify to the importance of midwifery as a branch of medical education, as well as to the necessity of teaching our students the practical details and management of labour in all its varieties. The methods adopted in the English schools differ materially from those in use on the Continent. In France, Germany, and Austria large lying-in hospitals are common, and it is not an infrequent practice to conduct difficult cases of labour in the theatre before a crowd of students when any obstetric operation is to be performed. In this country, on the other hand, such practice is unknown, and the sentiment of the public would doubtless be altogether opposed to its adoption. At the same time, if the practice were of such value that it supplied the student with a knowledge of operative midwifery which he could not otherwise obtain, and in this way proved conducive to the safety of the public, poor as well as rich, the sentiment would be unreasonable, and should be as far as possible treated accordingly.

Operations in midwifery differ from most other operations in this—that they are performed, not under the guidance of the eye, or of the eye and the touch, but of the touch alone. They are done within the pelvis, and little or nothing is to be seen; and witnessing the forceps applied, the perforator used, internal version or any other purely obstetric operation performed, can give the student little or no idea of the manipulation necessary to their safe performance. He can acquire a knowledge of the subject only by doing such operations himself. This knowledge would of course be best acquired on the living subject, under the supervision of a competent teacher. Cases of operative midwifery are, however, not so frequent as to permit of this, and we have to fall back on the next best alternative—operating on a well-made model. By the latter method the student can acquire a fair knowledge of the use of instruments, as well as a certain amount of skill in obstetric manipulation—a knowledge which will enable him to operate successfully and without inflicting injury in the great majority of cases. A knowledge of how to use instruments is not more important in operative midwifery than a knowledge of when to use them. The latter is far more difficult of acquisition than the former. Examination in the living pelvis alone can supply it; and it is in the education of the student in this part of midwifery that lying-in hospitals may prove of the greatest value. There are in London a considerable number of large maternity charities, in some of which thousands of women are attended every year, others in which the patients are counted by

hundreds. Several of the largest are connected with our medical schools, and the cases are attended by students. There are others in which all the work is done by midwives, under the supervision of physicians. This material is enormous; but it is not possible at present, and as the work is now carried out, to make the best use of it in the interest of the public or of the student. For teaching purposes a great part of it is not available. The women attended by the students from our schools dwell in wretched rooms scattered over wide areas, so that not more than one can benefit by each case, and it is not possible for that one even to derive that legitimate advantage from it which he would derive were the patients gathered within a small area where the teacher could personally superintend the labours. For this object lying-in hospitals are necessary, and nothing else can supply their place. There are four lying-in hospitals in London, and, with one exception, there is not the least attempt to utilise the material in them for teaching purposes. We cannot but think that it would be greatly to the benefit of the public, and especially of the poorer classes, were these made teaching in addition to charitable institutions, and were students of our medical schools permitted to enter them under some strict regulations. There would be no difficulty in drawing out a working plan which would prove mutually beneficial to institutions and students, as well as safe for patients.

WHEN commenting on the Report of the Royal Commission on Small-pox and Fever Hospitals, we referred incidentally to a proposal by Dr. BURDON-SANDERSON, F.R.S., for the construction of small-pox hospitals in such a manner that none of the hospital air could leave the hospital buildings without being first submitted to such a heat as would effectually destroy all organic and infective matter. Since then we find that the subject has received attention elsewhere, and there is evidently an increasing desire so to deal with our future small-pox hospitals as to prevent their becoming possible centres of infection, either by means of aerial diffusion or otherwise.

Dr. BURDON-SANDERSON'S proposal is to construct a hospital with one ward, for twelve patients, of an annular shape on a floor slightly raised above the surrounding ground, and if necessary to increase the accommodation by the construction of one or two more similar wards on a second and third storey. In the outer wall of the annular ward, and just above the floor level, are a series of openings into the external air, and in the inner wall, above the head of each patient's bed, and immediately opposite each of these openings, is a similar opening leading to a chamber which forms the centre of the ring. It is intended that this chamber shall be fitted with an extraction-fan, and in its roof would be fixed a gas furnace. All the windows would consist of fixed sheets of glass, and with the exception of doors carefully guarded by springs, and communicating with a corridor, there would, apart from the apertures in the outer wall of the ward, be absolutely no openings into the external air. Under these conditions, and by the aid of the fan in the central chamber, it is alleged that the air, having first passed over hot-water pipes, would be drawn into the ward through the openings in the external wall, that it would be conveyed at the rate of about one mile an hour over each

patient's bed, and that the beds being guarded on either side by septa projecting into the ward, the air would pass out of the openings near the ceiling level in the inner wall of the ring, from which point it would be drawn by the fan up into the furnace. By means of this operation each patient, having 1200 cubic feet of ward space, would be provided with 10,000 cubic feet of air per hour, and thus it would seem that a quarter of a million cubic feet of air per patient per diem would have to be treated by heat. Dr. BURDON-SANDERSON, as the result of his experiments, anticipates that no difficulty would be experienced in securing this end, and he has shown in his description of the proposed hospital how the various necessary administrative details could be attended to without disadvantage to the patients or the staff.

Another scheme, prepared before the publication of the Report of the Commission, was recently submitted to the Leeds Corporation by Messrs. HARDING, engineers of that town. According to this plan, inlets for fresh air are placed above windows which consist of fixed sheets of glass, and over each patient's bed is a funnel-shaped hood, communicating with a tube which passes round the walls of an ordinary oblong ward, and is then conveyed beneath the flooring to a furnace in an adjoining apartment. The furnace thus exercises an extracting power, and it is assumed not only that none of the air-inlets will become outlets, but that all the ward air will gradually be drawn up the hoods over the beds, and so on to the surface of the fire, where it would be deprived of its infectious qualities.

The principal difficulty which we anticipate in the actual working of a hospital in which every movement of air and all ventilation must, in order to complete success, be dealt with artificially, and in which all air must be drawn out of, instead of driven into, the building, is that of ensuring that none of the openings into the external air shall, under any circumstances, become outlets instead of inlets. Artificial methods of ventilation seldom answer all the ends they were hoped to have attained, and even where the current of air is with certainty directed into the intended channel it is often done at the expense of creating draughts. Of the two schemes we have noticed, we cannot but think that the desired end is more likely to be gained by the plan submitted to the Royal Commission by Dr. BURDON-SANDERSON. The warmer air in the upper part of the ward is the air which it is most essential to remove, and this would perhaps be best secured by making the outlets at a much higher level than the inlets, and by fitting both the machinery of the fan and the furnace with gas, which would continue to work without the need of that constant supervision which always becomes necessary in the case of an ordinary furnace dependent for its efficient working on human labour. Under any circumstances, if the temperature to which the out-going air were subjected in the furnace could be maintained at such a height as to ensure the destruction of all its organic matter with such instantaneous rapidity as would be essential, owing to the necessary velocity of the air-current, a very large proportion, if not all, of the infected air emanating from the patients would be destroyed before it left the hospital buildings, and such portion of it as might find egress by air inlets not sufficiently under the control of the general ventilating machinery, would probably be so

small that even in connexion with a building containing some thirty-six beds, it would never lead to that mischievous condition of atmosphere in the neighbourhood of the hospital which appears to need for its production the aerial emanations of an aggregation of at least some such number as thirty small-pox patients. In short, it is quite possible the suggestions which we have commented on in this article may ultimately be found to indicate a remedy for the dangers which have been shown to attend upon the isolation of any large number of small-pox patients in the neighbourhood of centres of population.

AMONG the causes which lead to the numerous rejections at the College of Surgeons and some other examining boards, we must not omit to take into account that very important one which in many cases lies at the root of the matter—viz., an imperfect preliminary or school education. This has been brought forcibly under notice by the results of the examination instituted last September, at the suggestion of the Medical Council, by the Cambridge Local Examination Board, and also by the September examination held by the College of Preceptors. In both these examinations the rejections were very numerous, and the ignorance displayed by many of the candidates was remarkable. The seriousness of this deficiency can scarcely be over-estimated. If the foundation-stone of education laid at school be bad, the probability is that the whole subsequent structure will be bad also. The ill-trained schoolboy will prove an indifferent medical student; will probably be rejected at the examinations; and when, after sundry failures he manages to pass through the portals of the profession he is not likely to meet with great success in it. Whatever may be the curriculum of medical education, whatever may be the provisions and arrangements of examining boards, whatever may be the efforts of authorities and of teachers—from the Medical Council to the private tutor,—this radical school defect cannot be overcome. To it we would call the serious attention of parents and schoolmasters, and all who have the charge of boys intended for the medical profession. Even from a pecuniary point of view the curtailment of school education is the worst economy. It probably entails rejection, with attendant disgrace, at the medical examinations; a longer period, with proportionate expense, in medical education; and a lower status in the profession. As the lad starts from school, so will he usually go on in the profession. The measure of his success in the latter may commonly be estimated by the quality of his school training and his proficiency in school knowledge. It matters not so much *what* he has learned as *how* he has learned it. The tendency, perhaps, is to sacrifice quality in learning to quantity. A little well and thoroughly mastered is far better than a larger amount held loosely and indifferently. Let a good school be carefully chosen, a school in which there is some assurance that the subjects, whether linguistic, mathematical, or physical, are well taught, with a view to the mental training of the boys, and let the parents or guardians have an eye on the matter, and ascertain for themselves that this is being done, and evince their anxiety about the school teaching as well as about the school games—about the mental as well as about the bodily gymnastics; in short, use their best endeavours that a sound educational

basis has been laid before the boys enter upon their medical studies. They may then have good confidence that the result will be satisfactory; at any rate they will not have themselves to blame if it be otherwise. We are well aware that a variety of qualities, mental, moral, and physical, combine to give success in the medical profession. There is scope in it for a greater variety than, perhaps, in any other line of life. In no other do the personal element, the warmth of heart, the vigour of character, come so much into account. Happy are they to whom Heaven has granted these qualities in large measure; happier still, and certain of success in life, are they in whose case Heaven has added also the wise and continually watchful solicitude of parents that their early mental and moral training should be good.

## Annotations.

"Ne quid nimis."

### MEDICAL QUESTIONS IN PARLIAMENT.

A WEEKLY reference to this department of THE LANCET will show that few questions of any interest in medical or sanitary matters escape the attention of our reporter. No doubt many questions are put with little practical purpose, and some, it may be feared, with little more intention than to worry a minister or department; but, nevertheless, the power of questioning responsible ministers in their place in Parliament is a most valuable one, and leads sometimes to the correction of misrepresentations, sometimes to improved administration of the law, and sometimes to an amendment of the law itself. It is so difficult to get at the official and permanent heads of departments, and the forms of the House are withal so unfavourable to legislation, that if there were not the hope of doing some good by a plain and direct question to a minister, we should be ever so much worse off than we are. The use of questions in Parliament has been well illustrated in the present short and exceptional session of Parliament. In the very nature of it, work and legislation have been restricted to questions of procedure; but the questions put have covered a large amount of ground, and have elicited information as to facts and as to the intentions and views of Government which is interesting. The questions have ranged from the therapeutical value of phosphate of potash in scurvy, or the efficiency of the conduct of the medical officers of the expedition in Egypt, to the importation of drugs into Japan, or to the better supervision and education of the children of gipsies and other nomads. The answers, if for nothing else, are always worth attention for their discretion, and for what moralists would call the "economical" amount of reply and information they contain.

### THE PARKES MUSEUM.

THE newly appointed Council of the Parkes Museum have entered upon their work with a becoming sense of the possible importance of the institution over which they have been called upon to rule. They have, rightly we think, determined to go to very considerable expense before opening the museum to the public, and there can be no doubt that the work which is now being carried out in the new premises will add immensely to the efficiency of the museum as a centre for the practical teaching of hygiene. It has been determined to considerably enlarge the existing skylight of the chief hall of the museum, and to carry a light ornamental iron gallery completely round the main hall and the council-room, which will also be used as a library. These alterations will entail an expenditure of nearly four hundred pounds,

and the Council very properly hesitated to embark on such an undertaking without seeing its way with tolerable clearness to the source whence the necessary funds were to be derived, and it is right to state that the ability of the Council to proceed with this most necessary work is due to the public-spirited action of its individual members, who have given donations or promised subscriptions which we believe amount to nearly £500 in the aggregate. This action on the part of the Council, composed as it is entirely of professional men of high standing, will serve as a guarantee of their earnestness and *bona fides* in the work which they have in hand, and will certainly ensure an adequate and loyal support for the museum from the professional and general public. Not only have the gallery and new skylight been determined upon, but, as we have already mentioned, the whole of the drainage arrangements have been undertaken by Mr. Rogers Field, who has generously offered to superintend their construction and bear the whole expense of them. These arrangements will be so constructed that they will admit of ready display for the purposes of teaching. With regard to the heating arrangements, the Council have determined to utilise for this purpose as great a variety of apparatus as possible. More than one of the stoves and grates which were premiated at the Smoke Abatement Exhibition will be used, and economy of fuel, consumption of smoke, and the combination of heating and ventilating, are the principles which are guiding the Council in their selection. One fire-place is, we understand, to be constructed on the principle advocated by Mr. Fletcher of Warrington, and this work will be carried out under the personal supervision of Captain Douglas Galton, the Chairman of Council, whose practical knowledge of heating is well known. The details of the lighting have not yet been finally settled, but on one point we understand the Council to be unanimous—namely, that no gas-lamp shall be admitted to the museum which does not provide for the escape of the products of combustion from the apartment. Now that the museum has ceased to be connected with any one place of instruction, it will be of considerably more service than heretofore to all teachers of hygiene in the metropolis or its neighbourhood, and it is contemplated to give every facility to teachers and lecturers at medical schools and elsewhere for bringing their students to the museum for the purpose of practical instruction. The room appropriated for a council-room and library is admirably adapted for its purpose, and the gradually increasing number of works and periodicals bearing on sanitary subjects which are to be found upon its shelves cannot but prove an attraction to students, and a strong inducement for all who are interested in the museum to take up their membership. All who may wish to become members of the museum should communicate with the Secretary, Hon. Secretary (Dr. Dawson Williams), or the Treasurer (Mr. Berkeley Hill). All letters should be addressed to the Parkes Museum, 74A, Margaret-street, W.

### HEALTH OF THE TROOPS IN EGYPT.

WE are happy to learn that the latest intelligence from Egypt shows an improvement in the health of the troops, the percentage of sick having fallen to ten, and the mortality from all causes, including enteric fever, being much diminished. The information on the subject of the sickness and mortality has been very meagre, nothing having as yet been published officially. But, accepting as correct the numbers transmitted from Cairo, it appears that in the force stationed there, numbering 8725, there have been 1683 admissions and 51 deaths from Nov. 1st to Nov. 26th, inclusive. These figures give the annual ratio of 271 admissions and 8.21 per cent. of the strength. Considering the hardships the troops had gone through, and the causes of disease to which they had unavoidably been exposed, especially the condition

water which for some time they were compelled to, this rate does not appear to be greater than might been expected ; indeed, it is much under what occurs at stations in India, where the troops have not been exposed to any unusual hardship or privation. If the results for the whole of the troops in Egypt were published, the results would probably be much more favourable ; and, considering the reduction which is now steadily taking place both in the fresh cases of sickness and in the number of deaths, we think there is every reason to hope the health of the troops will soon reach a satisfactory standard.

RHEUMATISM OF THE BRONCHI.

UNDER the rather alarming, if etymologically accurate, name of "rheumatic leucinoitis," Dr. Buckler, of Paris, contributes to the current number of the *American Journal of Medical Sciences* a paper of some interest and value. States that for many years past he has believed in the existence of a condition of inflammation of the bronchial tubes in which the fibrous structures are primarily and the mucus membrane solely involved. It is a condition which he thinks remarkably frequent, and of considerable gravity, from secondary pneumonia it is liable to induce. Moreover, the recognition of such an affection, he maintains that they are able to complete the clinical picture of bronchitis which Laennec left unfinished, and may find here especially an explanation of those severe and persistent cases of so-called "dry catarrh" the pathology of which is veiled in obscurity. It is, as we have indicated, many years since Dr. Buckler first wrote on the subject, and, as he himself states, he has had to encounter much difficulty in the acceptance of his views. He has therefore returned to the subject with the additional force of several marked examples of the affection, which he maintains to be distinctly of a rheumatic character, from its supervening in the course of acute rheumatism, and from its occurrence under conditions favourable to the production of rheumatism, as well, finally, in the state of the urinary excretion. As to the physical signs of rheumatic "leucinoitis," they are as notable for their absence as snakes in Iceland. Indeed, the diagnosis is based upon a continued, distressing, hard, dry cough, for which physical examination reveals no sign ; the mucous membrane not being swollen or inflamed, there is presumably no change in the calibre of the tubes and no excess of bronchial secretion, and the bronchitis is therefore mute. But in several cases the condition leads to pneumonia, or at any rate to pulmonary engorgement, which is made manifest by physical examination. Dr. Buckler goes so far as to attribute the excessive mortality from bronchitis, especially that which occurs in London during the prolonged prevalence of fogs, mainly to this hitherto unrecognised affection ; and he details the case of a patient who attributed his ailment to this cause. He was a man of about forty years of age, and always of good health. He said, in answer to Dr. Buckler's queries: "I got this cough at the time of the great London fog which happened nearly eight weeks ago ; it has been all the time the same as I have it now. I went for three weeks as an out-patient to the Westminster Hospital, but at the end of that time my cough was no better than when I first went there. My worst spell of coughing begins about four o'clock every morning, and continues usually without little stop until seven. I have never had the slightest pain. My appetite is good. Going upstairs makes me short-breathed, and causes a feeling of suffocation. I sleep well when not disturbed by cough." There was only an occasional faint sibilant rale, and Dr. Buckler thought there was some evidence of commencing pulmonary congestion. Acting on his view of the case, he prescribed salicylate of soda, with speedy relief to the bronchial symptoms ; and it may be

added, as to the treatment of these cases, he prescribes the salicylate except when the urine, instead of showing an excess of urates, is found on the ammonia test to contain an excess of phosphates, when fresh lemon-juice is most useful. How far Dr. Buckler's idea as to the prevalence of this form of rheumatism is borne out by general experience we do not know, but the profession will doubtless be prepared to test the validity of his contention and the value of the line of treatment he suggests.

THE WEIGHT OF WOMEN'S CLOTHES.

THIS is a phase of the dress question which has been too much overlooked. The clothes worn by women are, as a whole, far too heavy ; and, by a perversity of fashion, they receive an enormous increment of weight at this season in the shape of cloaks or mantles of sealskin or plush with quilted linings. The attention of medical practitioners needs to be specially drawn to this matter, in order that they may remonstrate with their female patients, and also avoid misconception as to the actual strength of some who complain of fatigue in walking, which may be mistaken for a token of weakness, whereas it is only natural exhaustion from carrying a burden that few strong men would care to bear. There are even worse evils than mere fatigue consequent on the practice of loading the body feminine with the outrageously heavy outer garments now in vogue. Not only are the ordinary movements of the legs and arms injuriously impeded, but the waist is encircled as with a belt or hoop, to which a load heavier than a felon's chains is attached, and the shoulders and chest are compressed by an additional burden. Breathing is laboriously performed, and the contents of the trunk and pelvis are thrust down with a force which, if represented in pounds, would occasion considerable surprise. We venture to suggest that, as a matter of more than curiosity, medical men should ask their female patients to ascertain precisely the total weight of the clothes they wear in-doors and out. The matter is by no means unimportant. We have reason to think that not a few of the maladies from which women suffer acutely, and the general weakness and depression of the muscular and nervous system of which they very commonly complain, will be placed in an entirely new light when the facts to which we now call very serious attention are fully known.

THE "NON-RESTRAINT" LUNATIC SYSTEM IN AMERICA.

IT is amazing, as well as amusing, to read in a recent number of the *Boston Medical Journal* an announcement to the effect that the medical superintendent of an asylum numbering 800 (!) inmates, "many violent and noisy, making them difficult to control," has dared to adopt the non-restraint system. Of course it is only at one asylum that this temerity has been shown, and even there the doctor stands on his reserved right to restrain either by the usual devices or by the use of sedatives, if he thinks it necessary. By-and-by, if this sort of thing goes on, some one in connexion with a public hospital will be making the public hair stand on end, and at the same time earning for himself eternal gratitude, by venturing to give the victim of a formidable operation chloroform ! Happily, however, it is only in respect to the management of the insane America lags about forty years behind the rest of the world and is now just beginning, in a very small and limited way, to perceive what other peoples have long recognised—namely, that insanity is not either a "visitation" or a crime, but simply a disease, which only needs to be treated on medical principles to be brought within the pale of human influences, when its victims will be found not less easily manageable than the sane.

## DEATH IN PRISON.

WE regret, after only a short interval, to call attention to another death in prison under circumstances which call for explanation on the part of the Commissioners who are responsible for the working of the new Prison Act. In the present instance we are pleased, however, to state that no blame attaches to the officials in charge of the prisoner, and it was not their fault, nor that of the prison surgeon, that the deceased remained for several hours after the commencement of his fatal illness without medical relief being afforded, and in fact died before the medical officer of the prison could see him. The reason for this neglect is tersely stated in the evidence of the governor of the prison, "There are no arrangements under which, in event of any sudden illness or other emergency, and the surgeon or assistant-surgeon being absent from the town, I can call in another medical man to attend a prisoner." Such evidence is an emphatic condemnation of the niggard and parsimonious administration of our prisons under the working of the new Act. The unfortunate prisoner, who had been an inmate of Huntingdon Gaol for some time, was suffering from heart disease, on which account he had been excused from hard labour, and had been under treatment and visited every day, though apparently not ill enough for removal to the infirmary. On the day of his death he was taken ill at 6 A.M., he remained ill all the morning, and urgent symptoms developed till 11.40, when the authorities, becoming alarmed, sent off for the medical officer. This gentleman happened to be on his country rounds; the message reached him between 1.30 and 2 P.M., and he at once attended, but too late. The man was dead. The public, who know nothing of the conditions under which the Commissioners of Prisons secure medical attendance for the inmates of their gaols at the least possible expense, will probably feel inclined to lay the blame on the medical officer for being out of the way. It will be as well therefore to explain that the Commissioners, in order to secure medical services at as cheap a rate as possible, permit the holders of the appointment to engage in general practice. In this way they are enabled to secure the services of first-rate men for something like £100 or £200 a year, instead of paying £700 or £800, which would be the case if they were called upon to devote their whole time to prison duties. Now it is impossible for a man to be in two places at once, however zealous and energetic he may be, and therefore it is incumbent on the Commissioners to provide that in cases of emergencies, in the unavoidable absence of the prison surgeon, the nearest available medical man be called in to act for him till his return.

## RESIDENTIAL CHAMBERS FOR STUDENTS.

WE have always most strongly urged the desirability of an institution on the lines of the "Union" Societies of Cambridge and Oxford for the benefit of the students in attendance at our London medical schools, and a plan by which good residential chambers could be made available for such of them as would desire to adopt a collegiate form of life would also be a great boon, if good management and a proper system of discipline could be insured. Without these they would be unmixed evils. We should, for our own part, prefer that the various schools and colleges themselves establish residential chambers, reading rooms, &c., rather than that a large central institution should be founded, for in the former case the management and discipline would devolve on the proper authorities instead of being casual and inefficient, as would be more likely to occur under the latter system. At King's College and at St. Bartholomew's such residences, although by no means sufficiently numerous and not properly supplemented by recreation rooms, &c., do exist, and are in much demand both by parents for their sons and by the

students themselves. It would be a great advantage to medical students if chambers in connexion with the schools were general instead of being limited as at present, for undoubtedly many of the faults and much of the idleness now urged against those engaged in the study of our profession, are directly due to a want of supervision after lecture hours and to the dreariness and unsuitability of the lodgings in which, under the present régime, they are compelled to reside. We have our fears, however, whether any central scheme could secure the proper organisation essential to its success. A club—with reading and debating rooms, a gymnasium and a music room, &c.—is quite another and a more modest proposal. The necessary supervision and arrangements could be more easily arranged than if a residential college were added thereto. The "Unions" at the universities are very successful, and we can see no reason why, provided that it be worked by the proper authorities, and with great care and determination, a similar institution should not be well carried out in London, with signal advantage to the very numerous body of medical students now necessarily left to themselves in our metropolis. The dangers which threaten its success are obvious to every one, and can only be avoided by the use of circumspection and care at the outset, and to secure these great desiderata a very prudent selection of the executive is imperative. It is given to very few to understand the wants of the student and at the same time to command the qualities necessary to the successful management of a club or a residential college.

## THE SANITARY STATE OF YORK.

THE recent report issued by Mr. W. S. North, medical officer of health for the City of York, and of which we gave an abstract last week, has attracted a large amount of attention. During the third quarter of the year there had been in York a very high mortality from zymotic diseases, and especially from diarrhoea, and this is, in the opinion of Mr. North, a marked indication of the general prevalence of bad sanitary conditions. Privies and ashpits in which human excreta and garbage lie decomposing, remain in certain parts of the city for weeks and even months without being cleaned out, polluting the air and soil by their filthy emanations and soakage. Ill-constructed drains, frequently passing under living rooms, convey foul air into dwellings; ill-ventilated sewers lead to sewer air being forced up house drains; and piggeries, cowhouses, and slaughter houses are a source of nuisance. These are essentially the conditions which, according to Mr. North, are calculated to lower the health of the inhabitants and to render people susceptible to disease. Especially are their effects noticed in the case of infants whose vitality cannot resist such noxious influences, and hence doubtless the large diarrhoea mortality for which York has become noted. At a recent meeting of the York Town Council several councillors gave evidence of their sense of the responsibility attaching to their position as members of a board dealing with the sanitary interests of the city, for though admitting that Mr. North's report had produced considerable consternation and surprise, they felt that they were fortunate in possessing as medical officer of health a gentleman who had the courage openly to state his opinion as to the sanitary shortcomings of the city. Others, it is true, held a different opinion; they would either have kept the matter quiet because of its damaging influence on the value of property within the city, or they would have solaced themselves and others by attributing the diarrhoea mortality to "atmospheric causes." They were, however, in a minority, the report was agreed to, and we may look hopefully towards the adoption of measures for the gradual extinction of conditions so injurious to health as those now obtaining in York. As regards fatal diarrhoea, we learn that two of its principal factors are at work in York. There is a steady overcrowding of houses

on site in progress, and hence the density of population in area is becoming a matter of serious importance. And not only so, but the limited open space about houses is occupied by conditions ensuring the pollution of the air breathed. The Town Council should set itself earnestly to remedy these conditions, on the one hand by adopting by-laws which will for the future ensure ample open space about newly erected houses, and on the other by securing a better system of closet and ashpit construction, together with regular and frequent scavenging. When these matters have been dealt with, and when sewers and drains have ceased to pollute the air which infants breathe, then it will be time enough to inquire whether the atmosphere is at fault in the production of an essentially preventable disease.

#### POISONOUS MUSHROOMS.

THE question of the poisonous nature of certain commonly-eaten mushrooms is again attracting some attention, and not without reason, for, as is generally admitted, the study and investigation of the properties of the edible fungi is one of the most difficult which can fall to the lot of the toxicologist. Our acquaintance with the subject is limited, for we know little or nothing of many of those active principles which occasionally produce such direful effects. Professor Ponfick, of Breslau, has recently made a series of experiments with the common mushroom, and his practical results are of considerable interest and value. He considers that all common mushrooms are poisonous, but that cooking deprives them more or less completely of their deleterious qualities. The repeated washing with cold water to which they are usually subjected to clean them dissolves out a portion of the poison, whilst the subsequent boiling completes the process. The water in which mushrooms has been boiled is a strong solution of the poison, and should be at once disposed of in such a way that it can do no harm. Professor Ponfick found that when dogs were made to eat 1 per cent. of their weight of raw mushrooms, they fell sick, but recovered; when the dose was increased to 1½ per cent. the poisonous effect was more pronounced, whilst 2 per cent. invariably proved fatal. The water in which mushrooms had been boiled was far more poisonous than the mushrooms themselves, whilst, after boiling, the fungi could be taken without the production of any symptoms to the amount of 10 per cent. of the dog's weight. Another point of interest is that dried mushrooms remain dangerous for from twelve to twenty days. They should be dried for at least a month, and are really safe only after four months' drying.

#### TYPHOID FEVER IN PARIS.

THE weekly admissions into hospital and deaths by this disease are as follows:—

For the week ending	Admissions.	Deaths.
Sept. 28th . . . . .	213	5
October 5th . . . . .	536	134
"   12th . . . . .	1001	250
"   19th . . . . .	741	244
"   26th . . . . .	406	173
Nov. 2nd . . . . .	423	125
"   9th . . . . .	341	112

The number of cases remaining under treatment in the hospitals on November 2nd was 2085. The deaths from typhoid fever among the population of Paris from the beginning of the year till November 16th have amounted to 2765, or in the annual ratio of 141 per 100,000. This is greatly in excess of the mortality from the same cause during the last decade, the highest proportion having occurred in 1876, when it amounted to 102·2 per 100,000. The average of the five years 1875–9 was 61·4 and of the two years 1880–81 it was 96·5, so that the deaths this year have exceeded by one-half the average of the latter period.

#### THE ASYLUMS BOARD AND THE HOSPITAL COMMISSION.

THE Metropolitan Asylums Board have, through their General Purposes Committee, had an interview with the President of the Local Government Board, with reference to the action they should pursue with a view to the future exercise of their powers for the protection of the public from the spread of infectious diseases. The Government have had it fully explained to them that the threatened litigation with regard to the Hampstead and the Fulham Hospitals, and the ejectment order which has been obtained with regard to the ambulance station at London Fields, have tied the hands of the Asylums Board, that they cannot properly perform their duties unless fresh legislation supercedes that under which they now exercise their powers, and which has been admitted to be defective. The Asylums Board have expressed their willingness to undertake the functions suggested by the Royal Commission, provided they receive the support of the Local Government Board. They have not, however, hesitated to throw the whole burden of the responsibility as to the future upon that Board; they have distinctly called upon the Government not to delay any further in taking action with regard to a matter affecting the health and lives of the community; and having regard to their previous experience under somewhat similar circumstances, one of their members has suggested that they should appeal directly to the Prime Minister.

#### COLD DRINKS IN COLD WEATHER.

THERE is a practice against which many persons, and particularly public speakers, need to be put on their guard—namely, drinking cold watery beverages in cold weather. The body becomes heated with the excitement and physical and mental exertion of addressing crowded assemblies. Nothing is more natural than to desire, under such conditions, a draught of some cold beverage. Now it happens that cold drinks are depressing in their influence, and the result of taking such draughts when performing more than common feats of strength and endurance, particularly in middle-age and advanced life, is to lower the tone of the nerve centres at a time when it is most desirable that they should be in exceptionally good working order, so that they may retain the vitality necessary to meet unusual need. So far as we are aware, the physiological effect of iced potations taken hastily when putting forth special strength and making a peculiarly large demand on the vital force of the nervous system, is either not understood or is forgotten. For the sake of the many zealous statesmen and politicians who do not seem to have given the need of special precautions in this particular a single thought, it is desirable to point out that the worst illnesses may, and do, proceed apparently from insignificant causes. This is one of the petty causes which may give rise to sad results.

#### SYPHILITIC ORGANISMS.

FURTHER observations of micro-organisms in syphilitic new growths have been published by Birch-Hirschfeld. He has examined a number of recently extirpated condylomata, and also a syphilitic growth in the wall of the heart, and has come to the conclusion that the organisms are not distinct rods or bacilli, as he formerly described them, but merely micrococci, and the appearance of rods is due to the linear association of a number of these elements. It is much more difficult to distinguish the individual elements than in the case of most micrococcal chains, because the organisms in syphilis are not round but oval, so that they are visible, not as points, but as short streaks. In most cases there are both monococci and diplococci; less frequently three

or five individuals are united, which curiously simulate long rods with rounded ends. In this the observations of Aufrecht are corroborated. For the demonstration of the organisms in recent preparations, Birch-Hirschfeld prefers potash, by the clearing action of which the micrococci are visible in the tissue on account of their strong refracting power. In a broad condyloma, they lie, for the most part, in small aggregations in the papillæ, and in many of the cells of the adjacent layer of the rete Malpighii. They may readily be detected in the juice of a recently excised condyloma, by tinting in the ordinary way; and of the various tinting agents, Birch-Hirschfeld concludes that fuchsin and gentian-violet are the best. In the growths in internal organs the smallest micrococci are most abundant, and the larger forms seen in the condylomata are seldom met with. In gummatous scars they have been sought for in vain. In more recent gummatous products they were most abundant in parts which had the aspect of growing granulation-tissue. They were partly scattered, partly aggregated into groups, which never exceeded a granulation-cell in size; they were also distinctly seen within cells. Many epitheloid cells seemed to have their nuclei filled with these organisms.

#### M. GAMBETTA'S WOUND.

OUR Paris correspondent writes:—On Monday morning, about eleven o'clock, M. Gambetta met with an accident at his country house at Ville d'Arzay, a small town just outside Paris, under the following circumstances. M. Gambetta fired off a revolver in his bedroom, and, forgetting that another barrel was still loaded, held it with his hand over the muzzle, when it went off, the ball entering the palm of the hand and making its exit about the middle of the forearm. The doctor of the place was immediately sent for, and the wound was dressed by him. Meantime, Dr. Lannelongue, hospital surgeon, was summoned to the patient from Paris, and arrived about two hours after, when he examined the wounds superficially, and dressed them temporarily with the intention of re-examining them more minutely the next day, which he did, and declared that there was no fracture, no artery wounded, and that he did not anticipate any complications, notwithstanding the fever which had declared itself, owing to which the patient was obliged to take to his bed. Dr. Lannelongue reports that the patient's condition is as satisfactory as possible, and that the fever has entirely subsided.

#### BOLINGBROKE HOUSE PAY HOSPITAL.

THE second report of this hospital is now published. The institution represents an experiment of interest both to the public and the profession. The promoters of a provident dispensary were led to found it on the double ground that the nearest hospitals, St. Thomas's and St. George's, were too far off; and, secondly, that many of the members were not of a class for which these hospitals were founded. Query, were they of a class by whom provident dispensaries, at their very unremunerative rates of payment for medical men, ought to be used? Be this as it may, the foundation of a pay hospital was an undertaking creditable to the boldness of the Vicar of Battersea, Canon Clarke, and the generosity of the residents of Battersea, Wandsworth, and other places. The principal comparative facts of the two years of its existence are as follows. In the first year the total number of patients, men and women, admitted was thirty-four, in the second sixty-five. The total payments made by the patients in the two years respectively were, in round numbers, £202 and £652; the total cost of maintenance, £407 and £858; of management, £84 and £34; the average days' stay of each patient in the two years respectively, twenty-seven and forty-four; the average weekly

payment of each patient £1 10s. 6d. and £1 10s. 1d.; the average weekly cost of each patient, £2 0s. 5d. and £2 0s. 11d. The number of beds available at the end of this year (Sept. 1882), as compared with the end of last, is twenty-eight against twelve. The table of occupations of patients who come from both London and the provinces is satisfactory. The diseases treated are chiefly phthisis, genito-urinary affections, and ophthalmia. It is noticeable that there is only one case of fracture, in an artisan. His friends agreed to pay 10s. 6d. weekly, but the day after admission his father called and removed him to a general hospital, "because he could get the same thing for nothing," though there was little doubt about ability to pay. We regret to see that the sum owing to the vicar as trustee has increased from £1300 to £1620. The services of the medical staff are still wholly honorary. It is premature to criticise so interesting an experiment. We shall content ourselves with recording its progress, and the perseverance of those lay and professional gentlemen who sustain it. It must be a valuable accommodation to persons of limited means, if it cannot be said at present to be remunerative to the profession or easy to Canon Clarke.

#### MR. TEALE ON ECONOMY IN USE OF COAL.

THE *Leeds Mercury* of Nov. 22nd gives an interesting report of a lecture delivered by Mr. Teale before a large audience in the Leeds Philosophical Hall on the previous night. The subject was the economical combustion of coal. Mr. Teale's genius is many-sided. It is above all practical and kindly. It concerns itself with many things outside what a narrower mind would consider its sphere. It has made its impress on modern surgery, but it can take thought for sound drains, cheap and effective fires, and all that will add to the domestic and municipal welfare of a community. The lecture we have mentioned is a striking illustration of this. It is a careful description of the various plans for securing a slow and complete combustion of the coals in our ordinary household fire-grates. Mr. Teale says the slow combustion of coals in a house fire depends on two conditions—first, that no current of air should pass through the grate beneath the fire; the second, that the space or chamber under the fire should be kept hot by being shut off from the outer air. He has been telling the public how for a few shillings one of two or three arrangements may be applied which will secure these conditions, and how by securing them a saving of one-fourth of coal may be effected, smoke and soot greatly diminished, and the ash refuse reduced by two-thirds. We cannot here detail the experiments by Mr. Teale and others which prove his assertions. The profession well knows that Mr. Teale is not likely to make any statements which he has not carefully verified. The particular "economiser" he advocated for ordinary stoves and grates, "applicable to every house," was a simple shield resting on the hearth, and rising as high as the bottom of the grate. Various speakers of authority confirmed Mr. Teale's estimate of the advantage of using "economisers." The profession will be induced by Mr. Teale's example to consider this question.

#### RETIRING PENSIONS TO MEDICAL OFFICERS.

MR. ROYLE, medical officer of the Milnthorpe district of the Kendal Union, lately tendered his resignation after twenty-six years' tenure of office. He naturally raised the question of a retiring pension. The guardians, notwithstanding a feeling speech from Mr. Barwise, pointing out that Mr. Royle's resignation was based largely on the ground of ill-health, declined by a large majority to make such a grant. Indeed only Mr. Barwise voted for it. This is poor treatment of an old servant who had served the Board well, and is scarcely consistent with the spirit of the law.

## LUNATICS IN PARIS.

THE report just issued by the Prefect of the Seine upon condition of the lunatic asylums in the department of Paris shows at what an alarming rate insanity is increasing in that city. At the beginning of the century there were only 946 lunatics in Paris, whereas at the end of last year the total stood at 8260, or, in other words, while the population has only increased threefold the number of lunatics has increased nearly ninefold. For the last ten years there has been an annual increase of about two hundred, the number of male and female lunatics being in the relative proportions of 54 and 46 per cent. The number of lunatics placed in asylums during last year was 2438, of whom 1293 were men and 1145 women, the ages of nearly half of them being between thirty and forty. Up to the year 1878 unmarried persons were in the majority, but of the lunatics admitted to asylums last year 1016 were married and 1002 single. With regard to their education, it is stated that 144 were highly educated, 1655 could read and write, 138 could only read, and 474 were completely illiterate. A third of them were either labourers or mechanics, and only 79 persons are described as following one of the liberal professions. More than 15 per cent. of the cases are attributed to overindulgence in drink, while among the moral causes, domestic trouble and sudden fright hold the chief places. The number of cases was greatest in the month of August, and fewest in January. About 180 of the lunatics placed under restraint last year were natives of Belgium, Germany, Italy, and Switzerland. The expenditure which their maintenance entails is partially reimbursed by the Governments of their respective countries. Thus Germany takes her lunatics back, but does not pay for their maintenance, while Russia and Switzerland defray all expenses. England, upon the other hand, neither defrays the cost of their maintenance abroad nor has them brought home. The number of cures effected last year was 683, or about one in nine, while the number of deaths was 1443, or one in eight, the majority of deaths and cures being among first-year patients. The cost of keeping up the lunatic asylums for 1883 is estimated at £192,000 for 8320 patients, but out of this sum £22,800 will be contributed by the families of the well-to-do patients.

## PUERPERAL FEVER AND ITS RISKS.

THE danger to nurses arising from attendance on cases of puerperal fever is illustrated by a case which lately came before Dr. Danford Thomas, the coroner for Central Middlesex. A woman named Ann Hart, aged seventy, nursed a Mrs. Breely in her confinement. Mrs. Breely suffered from puerperal fever and died. The day after her death the nurse was taken ill and was seen by Drs. Read and Hall, who recognised the presence of blood-poisoning. In spite of their efforts the patient died, and Dr. Hall stated at the inquest that in his opinion the poison entered the system of the deceased through the cracks in the skin of the hand and fingers. Cases in which nurses attending patients suffering from blood-poisoning, pyæmia, or puerperal fever, have become themselves infected, although rare, are not unknown. The hands and fingers are often the seat of small punctured wounds, such as pin pricks, the existence of which is overlooked or unsuspected, and these are often ways by which the poison of secretions of the patient suffering from puerperal fever may infect the system of the attendants. The risk of such occurrences may be greatly lessened, if not entirely removed, by the antiseptic precautions now frequently, although not generally, taken in cases of labour. These are important not only to the lying-in woman, but to the doctor and nurse also. Were the hands washed in a five per cent. solution of carbolic acid and afterwards

anointed with carbolic oil or unguent, the unsuspected spots capable of receiving infection would be rendered proof against it, and the hands might with comparative safety deal with the secretions and discharges of the puerperal period.

## REWARDS FOR THE EGYPTIAN CAMPAIGN.

TO the rewards which we announced in our last number as having been conferred on medical officers in connexion with the late campaign in Egypt, we have to add that of Companionship of the Order of the Bath conferred on Surgeon-Major H. B. Scott, M.D., who was attached to the personal staff of the Duke of Connaught. It is also announced that Mr. J. Watt Reid, C.B., the Director-General of the Medical Department of the Navy, is to be promoted to K.C.B., and that Brigade-Surgeon W. Jackson, C.B., who was recommended for special promotion by Lord Wolseley, is to have the honour of knighthood conferred upon him. We are glad to see that Mr. Childers, with his characteristic sense of justice, has found a means of rewarding Mr. Jackson without inflicting an injury upon the other medical officers, or establishing the dangerous precedent of recalling to the active list an officer who had been retired in conformity with the provisions of a Royal Warrant.

## WET CARRIAGES.

WE have on more than one occasion embraced an opportunity to warn the public against the danger of riding in hansom cabs with damp cushions. It is necessary to repeat the warning in consequence of the lumbago and inflammatory mischief, even extending to the kidneys, which are due to carelessness, not only in regard to cabs, but private carriages. During the recent wet weather attention has been attracted to the matter by the utter recklessness of servants, who, not being expressly told to put up the hood of victorias and open vehicles generally, have left them open until the cushions have been literally soaked by the rain. Not a few serious illnesses have already been traceable to this cause. It is useless to expect that coachmen or footmen will think of these things of their own motion. Servants are, as a rule, careless of the comfort of their masters and mistresses, and unless it be to save themselves a little trouble, they will not take thought for the soaking which an open carriage standing in the rain must certainly receive. It is no uncommon occurrence to find the cushion completely saturated; and when a susceptible person comes out of a heated house and sits for some time in a cold vapour bath, the consequences may be very serious indeed.

## THE RECENT OUTRAGES IN DUBLIN.

OUR Dublin correspondent writes:—In the affray between the police and some members of the secret societies which infest Dublin, on last Saturday night, one of the former was deliberately shot dead by bullet wounds from a revolver fired by a man named Dooley. A comrade of the policeman immediately fired on Dooley, and, after a struggle, he and another of the scoundrels were secured and removed in custody. Dooley was brought to Jervis-street Hospital, and on examination the following wounds were found to have been inflicted: a bullet wound through the right radius, a wound in the neck, and another which entered at the upper part of the right shoulder and passed through without injuring the bone; a contused wound on the back of the head, and a fracture of the left parietal bone, evidently produced by a blow from a revolver, were also present. He was not insensible, and was perfectly quiet and apparently unconcerned at his position. There was but little hæmorrhage. The pulse and temperature have both been normal, and in all probability the man will recover. Cox, the unfortunate

policeman, who was killed almost instantaneously, was shot in the back of the head, the bullet penetrating the bone and lodging in the brain; he also received a bullet in another part of the body. On Monday evening, a gentleman who lately served as a juror on the trial of Walsh for the murder of Constable Kavanagh was attacked by two men close to his residence, and stabbed in several places; he is now dead.

#### THE PRIX VOLTA.

THE French Government has decreed the creation of a prize of fifty thousand francs, which is to be called the Prix Volta, and awarded in 1887. The prize will be given to the author of the discovery which shall increase the facility of the application of electricity in one of the following departments (*qui rendra l'électricité propre à intervenir avec économie dans l'une des applications suivantes*): (1) as a source of heat, of light, of chemical action, of mechanical power, as a means of transmission of messages; and (2) in the treatment of disease. The second article of the decree states that *savants* of all nations may compete. This probably means that the prize is open to the whole world, although, as far as the wording is concerned, it might be refused to a practical discoverer on the ground that he was not a *savant*. The third article fixes June 30th, 1887, as the last day for putting in claims. A Commission nominated by the Minister of Public Instruction will examine into the merits of the discoveries specified by the competitors, and decide whether they fulfil the necessary conditions. The report of this Commission will be published in the *Journal Officiel*.

#### CURIOUS DEATH AND INQUEST IN CARMARTHENSHIRE.

THE *South Wales Daily News* has some very proper reflections on an inquiry into the death of a lady at Maesgwynne, near Llanstephan. This lady was found dead in her husband's bed. He was an epileptic. On the previous night two bottles of brandy were bought. Two servants and a child (a boy) lived in the house. No care seems to have been taken to ascertain whether the lady and her husband were alive or dead on the day of her death till seven at night, when a servant went in and found her dead, and the husband in a confused state, saying she was only asleep. A doctor was summoned to verify the death; but the coroner, in spite of the opinion of several jurors, would not take his evidence. Such imperfect inquests bring discredit on the coroner's office, and leave unmerited suspicion on families. Since then the husband of the deceased has died.

#### VACCINATION PROSECUTIONS AT BRIGHTON.

AN extraordinary story is told in an evening contemporary of evidence given before the Brighton magistrates in a case of prosecution for non-compliance with an order made for the vaccination of a child. Henry Holman, we are told, had been previously ordered to have his child vaccinated, and, having failed to comply with the order, was again brought before the magistrates. For the defence, it was stated that the defendant had actually taken his child to the vaccination station and requested that it might be vaccinated with pure lymph, but that the vaccinator told him "he had no pure vaccine lymph, and if he had he would not use it." The child was, therefore, taken away unvaccinated. The fact that the Bench overruled this objection in the case of Holman and that of other children where a similar contention was put forward makes it probable that this story was not believed. It cannot, however, be doubted that if left uncontradicted much harm will arise from its publication; and

we would, therefore, strongly recommend that no time may be lost in contradicting a statement so seriously reflecting on the conduct of a public officer.

#### THE HEALTH OF THE DUKE OF EDINBURGH.

WE are glad to be able to report that His Royal Highness is recovering from his indisposition. The Duke has been suffering from a pulmonary and nephritic congestion due to exposure on board the *Lively*. All serious symptoms have now passed away, but Dr. Wilks of Ashford is still in attendance on His Royal Highness. Though there need be no anxiety about a permanent recovery, it is obvious from the peculiar nature of his malady that many months must elapse before His Royal Highness will be able to undergo the fatigue and exposure incident to his professional vocation.

#### THE NAPOLEON OF CHESS.

OUR Newcastle correspondent, in his letter this week, alludes to the extraordinary playing of Mr. J. H. Blackburne, who has made a descent on Newcastle-upon-Tyne and tackled some of the hard-headed players of the North, playing blindfolded eight simultaneous games, and for the most part successfully. As if this were not enough, he proved his lasting powers and resources by engaging thirty players the next day; of these he vanquished twenty-seven, two were drawn battles, and he lost only one. Mr. Blackburne, in his style, refuses to be allured by the most tempting offers of his adversary; but, looking only to the end, hampers him, and at last swoops down in unexpected ways. It may be mentioned that, although his use of tobacco is by no means excessive during his play, he is particular as to quality, and he may be fairly classed in the category of "steady smokers."

#### THE SPEAKER'S INDISPOSITION.

GREAT sympathy and regret were expressed by members of the House on its becoming known on Tuesday evening that the Speaker was indisposed and unable to return to the chair. Though the House has not sat much later than midnight during the autumn session, the continuous consideration of the procedure rules, unrelieved by any breaks of committee work, as in an ordinary session, must have been very trying to Sir Henry Brand's health, and no surprise was felt by the House on Wednesday at the Deputy-Speaker, Dr. Lyon Playfair, again taking the chair.

#### MEDICAL SOCIETY OF LONDON.

ON Monday evening next the subject under discussion will be the preparation and examination of various tissues infected by bacteria. Dr. Heneage Gibbs will exhibit an interesting series of microscopic specimens illustrating tubercle, bovine tuberculosis, splenic fever, diphtheria, typhoid, &c.; and will subsequently give an account of the methods in which his results have been obtained. The clinical side of the subject will be discussed at a future meeting of the Society. We shall hope to publish in an early number the result of Dr. Gibbs' recent work on the subject of tubercle.

#### PORRO'S OPERATION.

THIS operation was performed on Monday by Dr. Godsen, in a lodging in Islington taken for the purpose, on a dwarf aged twenty-four, for extreme distortion of the pelvis. The child (a girl, living) weighs 8½ lb., and measures 20 in. in length. The height of the mother is only 52 in. Up to the present she is progressing most favourably. The operation was completed in just an hour.

## SIR THOMAS WATSON, BART.

THERE has been during the last week a continued decrease of strength, with distressing restlessness. The weakness is now so great that the end cannot be distant.

## WAITING-ROOMS AT RAILWAY STATIONS.

IF we may judge by the pestilential effluvia which reach the nostrils of passengers strolling into some of the waiting-rooms at railway termini in London, the sanitary condition of certain of the inner rooms appropriated to ladies must be most unsatisfactory. This is a matter which ought on no account to be overlooked. It is the duty of the officials of railway companies to see that their premises are in a condition conducive to health, and not in a state which can scarcely fail to favour the dissemination of disease. If proper precautions are not taken, the attention of sanitary authorities must be called to the matter, and at once.

## MR. ANTHONY TROLLOPE.

MR. TROLLOPE has made considerable progress towards recovery since the publication of our last report. The attacks of dyspnoea have now entirely ceased, and Dr. Murrell considers that there is every prospect of a speedy restoration to health.

IN the usual quarterly return of prevalent diseases presented to the Medical Society of the Paris Hospitals by M. Castel on Nov. 10th, it was pointed out that, although typhoid fever had raged so severely in Paris, the rate of mortality from this disease in the hospitals was lower than in the corresponding period of 1881. From lack of information as to the actual number of cases occurring outside the hospitals, it was not possible to say whether the same diminution in the comparative mortality characterised the epidemic as a whole.

THE *Citizen and Evening Chronicle* (Halifax, N.S.), reports the death of a boy while under the influence of chloroform, preparatory to the extraction of a tooth. A folded towel was used, on which were poured at intervals two teaspoonfuls of chloroform. Alarming symptoms supervening, artificial respiration was resorted to, nitrite of amyl was exhibited, and subsequently the patient was suspended with his head downwards; all, however, proved unavailing, and the boy succumbed.

THE death is announced of Dr. Henry F. Draper, Professor of Physiology in the University of New York. The deceased, who was born in 1837, was a son of the late Dr. J. W. Draper, author of "History of the Intellectual Development of Europe."

THE typhoid fever epidemic at Bangor appears to have almost completely disappeared. No deaths from the disease have been reported for more than a fortnight, and the number of convalescents has been reduced to fifteen.

MR. GEO. THOMPSON, jun., of Pitmidden, has placed £6000 at the disposal of the Senatus of the University of Aberdeen for the purpose of founding ten medical bursaries.

DR. J. BURDON SANDERSON, F.R.S., has been elected to the Waynflete Professorship of Physiology at Oxford.

SMALL-POX is reported to be ravaging the East African districts north of Delagoa Bay.

DR. A. E. SANSON has been elected Lecturer on Medical Jurisprudence and Public Health at the London Hospital Medical College. Dr. C. Meymott Tidy will lecture on Toxicology in the place of Dr. Rodgers, who resigned last summer.

## Public Health and Poor Law.

## LOCAL GOVERNMENT DEPARTMENT.

## REPORTS OF INSPECTORS TO THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

*Southborough.*—This urban district, which lies between Tunbridge and Tunbridge Wells, has been visited by Mr. Spear, one of the Local Government Board's medical inspectors, because of an outbreak of enteric fever. The district consists in the main of a small straggling town containing 3870 inhabitants; it has many natural advantages of site, soil, and scenery; and its main sewerage has been carried out satisfactorily. But most unfortunate mismanagement has been shown in other matters. The private drains allow of the retention and deposition of sewage matter within them, they exhibit defective and leaky joints, right-angled junctions are frequent in them, they are scarcely ever ventilated, and there is commonly a direct communication between them and the interior of dwellings. And further, the soil, which in consequence of drain defects has become polluted, is the source from which the domestic water-supply is derived by means of local wells, each house or group of houses having its catch-pit for liquid filth, and its well sunk in the same soil. Under these circumstances the story told by Mr. Spear becomes simple enough. The copious evacuations of an imported case of enteric fever are poured down without disinfection into the drains; the disease extends, leaky drains are found close to wells, and the consumers of the water sicken with enteric fever, until thirty-three persons residing in twenty-four houses have been attacked and four have died. In view of the urgency of the case Mr. Spear recommended that immediate disinfection of the sewers should be carried out, that a systematic inspection of house-drains should be at once commenced, that polluted wells should be closed, and a wholesome supply of water be delivered at houses daily by means of a hand cart, and also that further action of a permanent character should be no longer delayed. The sanitary authority appear fully to have carried out the more immediate of the recommendations, and it is to be hoped that they will for the future see the importance of securing, by means of efficient by-laws, proper drain connexions and of laying on a wholesome public water service.

## REPORTS OF MEDICAL OFFICERS OF HEALTH.

*Hastings (Urban).*—The medical officer of health for the Borough of Hastings, Mr. C. K. Shaw, has recently issued his quarterly report upon the health of this watering-place, the population of which is estimated at 44,239 persons. The birth-rate did not exceed 25.4 per 1000, showing the abnormal character of the population and of its age distribution. The 159 deaths registered within the borough were equal to a rate of 14.3 per 1000, which is stated to be a little below the average rate in the seven preceding corresponding quarters. It appears, however, that five deaths of residents of the borough were recorded in the Workhouse and Sanatorium situated outside its boundaries, while twenty-six of the deaths occurring within the borough were of "non-residents." Applying these corrections the health officer declares the "accurate death-rate to have been only 12.4 per 1000." The death-rate in the borough last quarter, whether we place it at 14.3 or 12.4, undoubtedly points to satisfactory health conditions, but we must demur to the assertion as to the "accuracy" of the lower rate. The correction of death-rates of watering-places for the deaths of "non-residents" is by no means a sure way to accuracy. In such cases the definition of a "non-resident" should always be stated, and the effect of such a definition upon the population should always be borne in mind. It would be interesting to know what proportion of the population of

Hastings would be pronounced "non-resident" if judged by the same standard. It certainly does not conduce to accuracy to exclude the deaths of "non-residents" and yet to count all "non-residents" in the population upon which the death-rate is calculated. It is reported that nearly 31 per cent. of the deaths of "non-residents" were due to phthisis, and it is beyond question that Hastings owes a considerable proportion of its increase of population to the suitability of its climate for persons of a phthisical tendency. The zymotic death-rate in Hastings last quarter was equal to 2.9 per 1000; the thirty-two deaths referred to the principal diseases of this class included twelve from diarrhoea and ten from whooping-cough. The fatality of the latter disease was, indeed, excessive for Hastings. Considering the incidence of summer diarrhoea, the proportion of infant mortality may be considered to have been satisfactorily low.

*Presteigne.*—Dr. C. J. Covernton, medical officer of health to the Knighton rural sanitary district, has prepared an exhaustive report on the sanitary condition of the town of Presteigne. The sanitary conditions of the place were such in 1878 that Dr. Airy inspected it on behalf of the Local Government Board, and, as far as we can judge, nothing seems to have been done there since that date. The place is without proper drainage or sewerage, the privy-with-pit is in general use, the lodging-houses are overcrowded and ill-regulated, and some of the schools are in a bad sanitary state. The conditions which may be deemed as satisfactory in the place are mainly so because of local advantages afforded by nature. Thus the wells are believed to be free from pollution because the rain rapidly washes all filth from the surface into the streets, and the street gutters to some extent answer the purpose of sewers, because a heavy rainfall secures their frequent and effectual flushing. Dr. Covernton, however, strongly urges the provision of a proper system of sewers, and the adoption of by-laws to regulate cleansing, nuisances, and lodging-houses.

*Cork.*—During the four weeks ending Nov. 4th the births registered amounted to 174, being equal to 28.0 per 1000. The deaths numbered 138, or a death-rate of 18.7. These returns, when compared with those for a corresponding period last year, show that the ratio of mortality remains practically unchanged, but they also indicate that there has since then been a decided diminution in the amount of febrile diseases of every description in the city.

At a meeting last week of the ratepayers of the parishes of Great and Little Waltham a resolution was passed approving of the scheme of sewerage and improved water-supply of the district proposed by the Chelmsford Rural Sanitary Authority.

## VITAL STATISTICS.

### HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5721 births and 3919 deaths were registered during the week ending the 25th ult. The annual death-rate in these towns, which had been equal to 21.3, 21.7, and 22.6 per 1000 in the three preceding weeks, further rose to 24.2 in the week ending the 25th ult. The lowest death-rates in these towns last week were 14.7 in Bolton, 19.7 in Wolverhampton, and 19.9 in Birkenhead. The rates in the other towns ranged upwards to 28.0 in Plymouth, 28.9 in Oldham, 32.2 in Hull, and 47.8 in Sunderland. The deaths referred to the principal zymotic diseases in the twenty-eight towns were 501, and within 9 of the number in the previous week; 120 resulted from measles, 110 from scarlet fever, 96 from "fever" (principally enteric), 88 from whooping-cough, 53 from diarrhoea, 29 from diphtheria, and 5 from small-pox. The lowest death-rates from these zymotic diseases occurred in Norwich and Wolverhampton, and the highest in Liverpool and Sunderland. Measles caused the highest death-rates in Liverpool and Sunderland; scarlet fever in Leeds, Blackburn, and Sunderland; whooping-cough in Birmingham and Preston; and "fever" in Sunderland, Liverpool, and Portsmouth. The 29 deaths from diphtheria in the twenty-eight towns included 16 in London, 4 in Liverpool, and 3 in Sunderland. Small-pox caused 2 deaths in London, 2 in Manchester, and 1 in Newcastle-upon-Tyne. The number of small-pox patients in the metropolitan asylum hospitals, which had been 70 and 73 on the two preceding Saturdays, declined to 68 at the end of last week; only 7 new cases of small-pox were admitted to these hospitals during the week, against

7, 12, and 16 in the three previous weeks. The deaths referred to diseases of the respiratory organs in London, which had been 330 and 345 in the two preceding weeks, further rose to 411 last week, but were 69 below the corrected weekly average. The causes of 97, or 2.5 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Newcastle-upon-Tyne, and in four other smaller towns. The proportions of uncertified deaths were largest in Oldham, Blackburn, Halifax, Sheffield, and Sunderland.

### HEALTH OF SCOTCH TOWNS.

The annual death-rate in the eight Scotch towns, which had been equal to 22.0 and 25.8 per 1000 in the two preceding weeks, was 24.3 in the week ending the 25th ult.; this rate was almost identical with that which prevailed last week in the twenty-eight English towns. The deaths referred to the principal zymotic diseases in these Scotch towns, which had been 89 and 98 in the two previous weeks, declined to 78 last week; these were equal to an annual rate of 3.3 per 1000, which was 0.2 above the rate from the same diseases in the English towns. The fatal cases of whooping-cough declined from 15 and 26 in the two previous weeks to 19 last week, of which 12 occurred in Glasgow, and 3 in Dundee. The 20 deaths referred to diphtheria showed a decline of 4 from the number in the previous week, and included 13 in Glasgow, and 2 both in Dundee and Greenock. The 18 fatal cases of scarlet fever, however, showed a further increase upon recent weekly numbers; 8 were returned in Glasgow, 4 in Edinburgh, 3 in Dundee, and 2 in Paisley. The 6 deaths referred to "fever," were below the average, although 3 occurred in Edinburgh. Seven of the 12 deaths from diarrhoea, and 2 of the 3 from measles were recorded in Glasgow. The deaths referred to acute diseases of the lungs in the eight towns, which had been 130 and 172 in the two preceding weeks, were 167 last week, and exceeded by no fewer than 75 the number in the corresponding week of last year. The causes of 111, or 19 per cent., of the deaths registered in the eight towns last week were not certified.

### HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 27.7 and 26.1 per 1000 in the two preceding weeks, rose to 29.2 in the week ending the 25th ult. During the first eight weeks of the current quarter the death-rate in the city averaged 24.1 per 1000, against 20.3 in London and 19.1 in Edinburgh. The 210 deaths in Dublin last week showed an increase of 21 upon those in the previous week, and exceeded any weekly number since the middle of May last. The deaths from the principal zymotic diseases, which had been 14 and 11 in the two previous weeks, rose again to 14 last week; they included 6 from "fever," 4 from whooping-cough, 2 from diarrhoea, and 1 each from scarlet fever and diphtheria. The death-rate from these zymotic diseases was equal to 2.1 per 1000, while the rate from the same diseases last week was 2.8 in London and 2.2 in Edinburgh. The deaths referred to "fever," which had been 8 and 3 in the two previous weeks, rose again to 6 last week. The 4 fatal cases of whooping-cough also exceeded recent weekly numbers. The deaths both of infants and of elderly persons exceeded the numbers returned in the previous week. The causes of 9 of the deaths were uncertified.

## THE SERVICES.

**ARTILLERY VOLUNTEERS.**—1st Cornwall (Duke of Cornwall's): Surgeon Arthur Austen Davis is granted the honorary rank of Surgeon-Major.—3rd Middlesex: Alfred Lingard, Gent., to be Acting Surgeon.

**RIFLE VOLUNTEERS.**—1st Suffolk: Surgeon and Honorary Surgeon-Major J. Mitford Ling resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the Corps on his retirement.—6th (West) Suffolk: Acting Surgeon John Sinclair Holden, M.D., to be Surgeon.

**ADMIRALTY.**—Fleet Surgeon Gordon Jackson to be Deputy Inspector-General of Hospitals and Fleets in Her Majesty's Fleet with seniority of the 24th ult.

In accordance with the provisions of Her Majesty's order

incil of April 1st, 1881, Fleet Surgeon George William Sutherland has been placed on the Retired List from the ult.; Surgeon John Christian has been placed on the Retired List of his rank from the 18th ult.

The following appointments have been made:—Fleet Surgeons Chas. A. Lees, M.D., to the *President*, additional, Jackson, promoted; James Flanagan to the *Duke of Devon*, vice Lees; and Stephen Sweetnam, to the *ce. vice Flanagan*. Staff Surgeon Edward W. Doyle to the *Valiant*, vice Sweetnam.

## Correspondence.

"Audi alteram partem."

### "PICRIC ACID AND SUGAR TESTING."

To the Editor of THE LANCET.

SIR,—I am sorry to have anything to say to detract from the value of the "happy accident" through which, on the evening of the 14th inst., Dr. Johnson, whilst using picric acid as a test for albumen, came upon what he believed to be an extremely sensitive test for grape sugar whether in the urine or elsewhere; but I cannot allow his letter upon the subject in your issue of the 18th to pass without a few comments upon it.

I have followed the directions given by Dr. Johnson, and the results of my own observations upon the employment of picric acid as a test for sugar stand thus:—When equal volumes of a saturated solution of picric acid and liquor potassæ are mixed a bulky precipitate of the comparatively soluble picrate of potash is formed. If now the contents of the test tube are boiled, the precipitate disappears, and a deep colour is developed. This change occurs without the addition of anything to the mixed picric acid and potash. On next pouring in some healthy urine and further boiling, notably deeper colour, now amounting to a claret red, is produced, and if the urine should be a concentrated specimen, the depth of colour may be very intense—so much so as to approach towards an appearance of black on being viewed by reflected light, but transmitted light shows it to be a deep claret red. If, instead of healthy urine, some diabetic urine be poured into the mixture of picric acid and liquor potassæ, a very dark colour is, on boiling, at once assumed, which appears almost, or it may be quite, black by reflected light; but it nevertheless, as shown by transmitted light, and also by diluting the product with water, consists of the same claret red character as in the other instance.

Without the addition of any foreign agent, then, to the picric acid and potash, boiling produces a certain amount of colour, healthy urine increases this, and diabetic urine increases it further still. The same kind of tint is throughout manifest. There is only a difference in the degree of colour produced, and by dilution with water the deep-coloured product yielded by the diabetic urine may be brought to resemble, so as to be undistinguishable, the test treated with healthy urine and the test taken alone.

Dr. Johnson suggests that the effect of picric acid is to intensify the colour produced by the reaction of caustic potash and grape sugar—the reaction known as Moore's test. If we refer, however, to "Watts' Dictionary of Chemistry," we find that the action of reducing agents upon picric acid is to lead to the production of picramic acid, which is a red-coloured principle. Various reducing agents are named which convert picric into picramic acid, and amongst them are the sulphides of ammonium, potassium, &c., which are susceptible of being generated by boiling urine with potash. The colour developed by boiling the mixture of picric acid and potash with a sulphide so resembles that produced by boiling it with healthy and diabetic urine that, as the result of observation, I could not distinguish any difference when brought to the proper extent of dilution, and I think it may be considered that the effect of grape sugar is to act as a reducing agent upon the picric acid instead of the picric acid intensifying the action of potash upon grape sugar.

A few words upon the subject of extent of sensitiveness that it is desirable for a test for sugar to possess looked at in relation to its employment as a qualitative clinical test. I believe it would be an absolute misfortune for a more sensitive test than the cupric test to be introduced into

general use. What is wanted for medical purposes is not to recognise the small fluctuating amount of sugar existing in healthy urine, but sugar when it reaches an amount to be of clinical significance. The ammoniated cupric test, which has been described by me and which I employ for quantitative purposes, and which is so sensitive as with the greatest facility to reveal not only the sugar but the amount of sugar existing in healthy urine, would be an exceedingly dangerous agent to employ as a qualitative test. Had I not been strongly impressed with this I should have long since introduced it to notice as a qualitative as well as a quantitative test. A good form of cupro-potassic test furnishes, I consider, exactly what is wanted by medical men. It resists being influenced by, or rather does not show the effect exerted by, the sugar present in healthy urine, but does reveal the presence of sugar when existing to an extent to be of clinical significance. A cupro-potassic test, if kept in solution for some time, loses its stability and becomes too easily influenced to be relied upon, unless certain precautionary measures are taken. I feel that I ought to be under some reserve in speaking about the cupric test pellets (supplied by Mr. Cooper of 26, Oxford-street) as they originated with me; but, at the same time, I believe I am serving the interests of medical practitioners in stating that experience has led me to regard them as supplying the safest test that can be used. I am, Sir, yours, &c.,

Grosvenor-street, Nov. 22nd, 1882.

F. W. PAVY.

P.S.—Will you allow me to add under the form of postscript to the letter which I sent you last week, and which reached you too late for insertion then, a few remarks suggested by the further communication contained in your last issue from Dr. Johnson. Appended to Dr. Johnson's letter is a communication from his son, which bears the impress of careful observation as far as it goes. Mr. G. Stillingfleet Johnson confirms what I have mentioned about potash alone and healthy urine giving the colour produced by sugar, and he enumerates several precautions as being necessary in the use of the test. He fails, however, to say anything about the effect produced by the presence of sulphides, which is identical with that produced by sugar. The sulphide produced by boiling albumen with potash suffices to give a deep colouration. Let some thoroughly washed precipitated albumen be dissolved in a boiling solution of potash and then a little of this be boiled with the mixture of potash and picric acid; the result observed is a deep colouration like that produced by sugar. I expect in Dr. Johnson's original observation on the two specimens of albuminous urine the albumen had something to answer for in the result he noticed. Again, a small piece of white flannel which represents hair may be boiled and dissolved in potash; a little of the liquid added to and boiled with the picric acid and potash gives an exceedingly strong behaviour. These are illustrations of how a reaction may be produced by a sulphide derived from the action of potash upon organic principles, and that a sulphide is actually produced by the action of potash upon the constituents of healthy urine is shown by the well-known fallacy that Moore's or the liquor potassæ test is open to from the presence of a little lead. Thus as a means of displaying the presence of sugar in healthy urine which Dr. Johnson lays stress upon, the indication is mixed up with error. Neither for qualitative nor quantitative purposes in relation to clinical utility do I consider the behaviour of picric acid and potash suitable for being turned to account as a test for sugar. Certainly as far as applicability to the requirements of the medical practitioner is concerned, I think it will be found that the discovery which Dr. Johnson so hastily communicated to you will prove devoid of value.

November 28th, 1882.

F. W. P.

### "SCURVY."

To the Editor of THE LANCET.

SIR,—I have read with interest the letters of Dr. MacDowall and Dr. Lucas on "Scurvy," which appeared in THE LANCET last week. I should like, however, to make a few remarks which, I think, will lessen the discrepancy that they both point out, as appearing to exist between Dr. Parkes and myself with regard to the antiscorbutic properties of lactic acid.

Dr. MacDowall observes that Dr. Parkes "teaches that lactic acid simply goes to form alkaline carbonates in the

body," and Dr. Lucas further points out that Dr. Parkes thought "fresh, and especially raw, meat useful in scurvy, and this is conjectured to be from its amount of lactic acid." Now, whilst these statements prove my position with regard to the view that I have advanced, that scurvy is induced through a diminished alkalinity of the blood, they are fatal to the suggestion I offered, that the inferiority of hung to fresh meat as an antiscorbutic is due to the presence of lactic acid, the result of muscle decomposition after rigor mortis and the increase of acid salts in the blood. A little consideration will show, however, the two views can be brought into harmony.

It is quite true that lactic acid goes to form alkaline carbonates in the body; but, then, what form do the carbonates take? If the base and acid are in due proportion, we may have the normal carbonate ( $\text{Na}_2\text{HCO}_3$ ), an alkaline salt with an alkaline reaction. This, most probably, is the condition in which the alkaline carbonates are formed in the living body, whilst the lactic acid formed in the muscle passes out into the circulation, and fresh portions of the base are being brought into contact for it to combine with. But, on the other hand, if the acid be in excess, then we have an acid carbonate ( $\text{NaH}_2\text{CO}_3$ ), the bicarbonate, an acid salt which, though it has an alkaline reaction, has the effect of an acid, since with neutral salts in the blood it is capable of forming acid salts with acid reactions. It is probably this form of carbonate which is derived from the lactates formed in muscles by decomposition after death, since the lactic acid is not carried off as soon as it is formed into the circulation; nor can a fresh supply of alkali be brought to it for it to combine with, so that acid lactates will in turn be reduced to acid carbonates. Again, free lactic acid developed from muscle in forming a lactate must take the base from some other salt, unless we assume that potash or soda exists uncombined in the tissues. The salt that is apparently robbed, as far as experiment enables us to judge, is the neutral phosphate of soda or potash. Lactic acid deprives this of one atom of its base, forming a lactate, but converting the neutral phosphate into acid phosphate. I may add that Maly has determined the presence of both acid sodium phosphate and acid sodium carbonate in blood.

Dr. Parkes' assumption, therefore, that fresh meat is antiscorbutic on account of the presence of lactic acid, is not opposed to my hypothesis that preserved or hung meat loses its antiscorbutic virtues owing to the development of this acid; since, as stated above, in the one case a small quantity of lactic acid and a sufficiency of base lead to the formation of alkaline salts, whilst in the other excess of acid and deficiency of base cause the formation of acid salts.

I am, Sir, yours obediently,

CHARLES HENRY RALFE.

Queen Anne-street, W., Nov. 28th, 1882.

### SPINA BIFIDA.

To the Editor of THE LANCET.

SIR,—In your issue of November 18th there appears a report of a discussion on the subject of spina bifida before the Clinical Society of London, and I am gratified to notice that some cases successfully treated are mentioned. My object in noticing the discussion is not to criticise the remarks of any of those who took part in it, but rather to name one or two observations or reflections which an increased experience has enabled me to make. Let me state in *limine* that I never treat a case without previously informing the parents of the extreme danger, and of the possibility of even instant death, and my assistants are instructed in regard to the certainty of a fatal result if the cerebro-spinal fluid is allowed to drain away.

It is now my impression that many cases are lost from delay in the treatment; the tumour grows, and thus the interior presents a much greater surface, so large in fact that the infant's feeble powers are unable to bear up against the local excitation requisite to effect a cure, and exhaustion follows. Pressure also, but very gentle pressure, ought to be useful in dealing with the larger tumours. Again, although very many lumbar cases have been successful, I am satisfied that the injection ought to be made with greater care than usual in low lumbar, or those almost coccygeal. This is the opposite of what might be expected, but from dissection I have learned that there the openings into the

spinal canal are often large, allowing the injected fluid to run further than is desired, and the shock is thus apt to be greater and more immediate.

In respect to hydrocephalus, it will occasionally occur in such cases, yet the history of at least two cases, known to me, shows that there was a threatening of hydrocephalus before operation, which afterwards permanently disappeared, as the patients are still alive and well. After injecting a spina bifida we should wait usually three weeks, longer if the tumour seems to be shrinking. The necessity for earlier interference might arise from circumstances too varied to be noticed here.

One case of meningocele was presented to me, which I injected not fewer than eight times with a solution of double strength (twenty grains of iodine and sixty grains of iodide of potassium in an ounce of glycerine), and which became perfectly consolidated. Nearly two years thereafter the child died of hydrocephalus.

I have been much pleased with the numerous successes of which, from time to time, I have been informed (now about forty), and my object in now writing you, is to lead, if possible, to greater security in an operation so critical.

I am, Sir, yours faithfully,

Glasgow, November 20th, 1882.

JAMES MORTON.

### ON THE DISTRIBUTION AND GERM ORIGIN OF CANCER.

To the Editor of THE LANCET.

SIR,—In the year 1875 attention was afresh directed to the geographical distribution of disease by the lectures of Haviland. Turning to one of the maps by which they were illustrated, that on cancer, we find that each bank of the Tweed about Berwick, of the Tyne at Newcastle, of the Swale, the Ouse, and the Humber in Yorkshire, the Trent about Nottingham, and the whole of our beautiful Lake districts are most fertile beds of cancer. Wales is nearly free except about the Conway and the Dovey; so are the manufacturing districts. Whilst Chester, Shrewsbury, Derby, Newark, and Lincoln are bad; as are, also, parts of Birmingham, the towns of Nuneaton and Lutterworth, and Huntingdonshire, Norwich, Stamford, and Peterborough. Cornwall is comparatively free except in the neighbourhoods of Falmouth and Bodmin. A belt of liability runs across Devonshire from Barnstaple to Exeter and Exmouth. Plymouth and the vicinity, with Totnes, is above the average; as, also, are Taunton, Axminster, and Bridport, Wells, Warminster, Blandford, and Poole in Dorsetshire. Bath stands high for mortality from cancer; so do Tetbury, Marlborough, Devizes, Shaftesbury, and Lymington. The Isle of Wight is all but free from cancer; and so is, likewise, the New Forest. Brighton and its district are bad; so are Hastings, Romney Marsh, Folkestone, Dover, Deal, Ramsgate, and Margate. Coming nearer to the metropolis, we find that in Chertsey, Guildford, Dorking, Epsom, Reigate, and East Grinstead cancer is pretty equally prevalent. The huge London district, with the exception of Uxbridge and Hendon, if we extend it to Oxford and Aylesbury, with St. Albans on the one side, to Ware, Epping, Ongar, and Shoeburyness on the other, constitutes one appalling cancer field. In London proper, strangely enough, the parish of St. Luke's, the swarming neighbourhood of Bishopsgate, crowded Bethnal Green, far away Old Ford, Bow, Poplar, the Isle of Dogs, savoury Rotherhithe, and fragrant Bermondsey, are almost entirely exempt. The west, the north, the south as far as Wandsworth and Clapham, have a second degree of mortality; the parts about the Marylebone-road, Regent's-park, and Primrose-hill are exceptionally bad. The returns for London go to show what is demonstrable in another way—that density of population, hard living, and laborious toil have very little to do in favouring the appearance and growth of cancer. Liverpool, like London, is situated on the banks of a large tidal river; it has a teeming and not over sober population; its deaths in 1878 from all causes out-numbered by a thousand the total of its births; and yet it, with this heavy general mortality, has an enviably small percentage of deaths from cancer. The reason being that it is surrounded by a district not liable to cancer—one, in fact, affording the lowest mortality from this cause. On the contrary, London is a huge cancer-bed in itself, and at every

ivable point the country for many miles round is almost ally bad. From these facts Haviland deduces the following conclusions:—All places and districts with a high mortality cancer present common characteristics. They have s or streams taking their rise in soft, crumbling rocks; volume of water is liable to overflow after violent rains sudden thaws, submerging the country to a greater or less nt on either side. The subsidence of these floods is very h more gradual than the rapidity with which they spread. ice a complete saturation of the soil to a considerable th, and from the surface a constant exhalation of decaying etable and organic matter. The land having never time urge itself from the poisonous malaria thus engendered, a store constantly in hand with which to welcome the t deadly overflow. Hence, I would submit, that it ows incontestably that cancer beds, once formed in this ion, must go on in an ever-increasing ratio in the manu- ture, propagation, and dissemination of germs which are ; sole efficient cause of cancer.

If this theory, which I contend the logic of facts estab- es, be correct, it throws much light on the increase of cer, its apparent hereditary nature, its liability to return, d preponderating influence amongst females, whilst it ords some hope of successful treatment.

I am, Sir, yours obediently,

Brook-street, W., Nov. 6th, 1882. R. S. GUTTERIDGE, M.D.

### DEATH AFTER ABDOMINAL OPERATIONS FROM HEART-CLOT, DUE TO DISEASE OF THE KIDNEYS.

To the Editor of THE LANCET.

SIR,—IN THE LANCET, November 25th, 1882, Mr. Lawson Tait asks "help from those who are familiar with kidney troubles." I doubt if he will find anyone who can help him to diagnose these granular kidneys before operation; or who can teach him how to prepare the patient so as to avoid possible evil results from their presence. I will, however, venture to tell him how to avoid such deaths as he describes. Let Mr. Tait protect his patients from sepsis during the operation, and he will avoid these deaths "in thirty-six hours from heart-clot," which simply mean deaths from acute septicæmia, or septic intoxication. "The details of the operations were found to be quite satisfactory." Why? Because the poisoning is so rapid that all secretion and excretion is checked, and all the vital processes are in abeyance. If the patients lived long enough septic peritonitis, pleuritis, &c., would develop, and we should not find the details of the operation so satisfactory. If Mr. Tait will consult Mr. Spencer Wells' admirable ovariectomy tables, he will find plenty of such cases as he records, but the deaths are not attributed to the diseased kidneys. The deaths are due to the disease of the kidneys, but only indirectly so. The septic virus is the real cause of death; the diseased kidneys cannot eliminate it, and the patients are poisoned right off with it; whereas if their kidneys had been healthy much of the poison would have been eliminated, and they might have struggled through, or died later with distinct post-mortem evidences of the septicæmia. The rapidly-ascending pulse is the characteristic feature of the condition; high temperature may be absent, or the temperature may even be subnormal; the poison acts too quickly and violently for the development of the tissue changes which cause high temperature.

It has become the fashion with those who discard Listerism to attribute all their mortality after operation to diseased kidneys. First it was the carbolic acid which caused fatal nephritis, or overworked these diseased kidneys. Now the carbolic acid has been sent to the right about, and still the patients with diseased kidneys die; so it is only the kidneys that cause death. I do not deny that carbolic acid recklessly used may cause death with these diseased kidneys or even without them; but I affirm that all evidence is in favour of the septic virus being the greatest danger to patients with diseased kidneys. Some time back I called attention to the fact that in spite of Listerism, patients who have been tapped will die of septicæmia. Mr. Tait would have none of it, but now he comes forward and in his own practice demonstrates the association between tapping and death after ovariectomy from heart-clot, which is simply death from septicæmia, as everyone with sufficient experience in abdo-

minal surgery knows. Perhaps Mr. Tait can tell me why he and those who agree with him, with regard to Listerism, are so afraid to admit a death from septicæmia.

I am, Sir, yours faithfully,

J. KNOWSLEY THORNTON.

Portman-street, W., November 27th, 1882.

### "SHOULD DISEASES OF CHILDREN BE MADE A SPECIALITY AT OUR GENERAL HOSPITALS?"

To the Editor of THE LANCET.

SIR,—Mr. Churchill's letter and your remarks thereon bring prominently forward the remarkable fact that by far the majority of those who leave our medical schools at the present time, to face the responsibilities of general practice, leave with a very inadequate knowledge of the diseases of children, although in all probability the major portion of their first patients will consist of children. Possibly under the idea that the greater includes the less, or that opportunities of frequenting the out-patient room of a children's hospital are not readily afforded, and do not pay from an examination point of view, they never familiarise themselves with the clinical examination and treatment of children whilst students, and find out their error only when fairly launched upon general practice. It is beyond all doubt a fact that not only the average student, but by far the majority of the men who have held the most valued resident posts at our large hospitals, leave to enter upon practice unfamiliar with the ordinary complaints of childhood, and are completely at sea in the matter of prescribing medicine or a diet for a child. To take one familiar instance: How many children are sent into a fever hospital in the course of a year suffering from acute pneumonia, the sender unfamiliar with the facts, that croupous pneumonia in children as often attacks the apex of the lung as the base, that it is frequently attended with delirium, and that the classical physical signs may be latent or may never appear. In some cases, no doubt, men have the means and the wisdom to take a clinical assistantship or house-surgeoncy at a children's hospital or dispensary before entering upon private practice, but this can only be the privilege of the few; the majority will still be dependent upon the clinical instruction to be derived from lectures and visits to the out-patient room or wards of a children's hospital or special department of a general hospital. How is it possible to facilitate the study of children's diseases at our medical schools? I have often been struck by the absence of any questions on diseases of children, except, perhaps, one or two stock ones, in the medicine papers set by the various examining boards; no one wishes for a separate examination paper, but surely, considering the importance of the subject, it should fairly claim a fair share of attention. Why, also, will not the examining boards recognise three months spent in attending the practice or filling the post of clinical assistant at a children's hospital, as they do at a lunatic asylum, to count as part of the time devoted to clinical study? I must confess, Sir, too, that I cannot agree with you when you deprecate the giving of a course of systematic lectures on diseases of children. No one doubts that the multiplication of lectures is a weariness to the flesh; but surely a course of, say, ten or twenty lectures on a subject that bears so closely on the daily work of every ordinary practitioner would be at least of equal value to the courses regularly delivered on botany, comparative anatomy, toxicology, or lunacy? Need there be any real severance of the course from that of systematic medicine because given by a second person whose daily work renders him specially familiar with the subject? The classical lectures of Watson and West are found, or ought to be, side by side on the shelf of every practitioner: would anything be gained by binding them up together? Surely the lecturer on medicine will not feel himself aggrieved because he is relieved of the necessity of discoursing on diseases incident to birth, or on the athrepsia of infants or even congenital syphilis or whooping-cough? While, on the other hand, it would be absurd for the children's course to cover the whole ground occupied by pneumonia or typhoid fever because they both happen frequently to occur in childhood. If these lectures are illustrated by clinical teaching in the out-patient room and wards, I cannot but think that they would be productive of

good and help to fill up a hiatus that undoubtedly exists in the teaching arrangements of our medical schools. A special department may possibly be organised at some general hospitals; but I fancy a good many will be found to oppose the emptying of an adult ward to fill it with children. In spite of the distance which often exists between the various institutions, I believe if regular clinical instruction is given at the various children's hospitals in London and in the provinces they will not fail to attract students, and facilitate the acquirement of knowledge closely bearing on their future career. As a welcome sign of the increased interest taken in the subject comes the newly created section for diseases of children at the British Medical Association meeting to be held at Liverpool next year.

I am, Sir, yours faithfully,

HENRY ASHBY,

Lecturer on Diseases of Children at the  
Owens College.

### "THE CONTAGIOUS DISEASES ACTS."

To the Editor of THE LANCET.

SIR,—In THE LANCET of October 28th there is a short article by my friend Mr. Rawdon Macnamara, advocating the extension of the Contagious Diseases Acts to Dublin; will you kindly allow me space for a few observations on that article?

In the first place, Mr. Macnamara, no doubt unconsciously, does great wrong to those gentlemen who have all along steadily contended for the extension of the Acts. He takes up the ground that they have always approached the question solely from the man's point of view, ignoring the woman altogether. On the contrary, they have always argued that the system benefits the woman in securing her better health, greater decency of life, and opportunities of reclamation, which she could not otherwise have (see the evidence of Dr. Barr before the Parliamentary Committee).

Secondly, Mr. Macnamara says that those who oppose the Acts contend that any beneficial results (if there be any) are confined to the male sex, they also ignoring the woman. So far from this being the case, those amongst us who are opposed to the system of regulated prostitution base our opposition on our conviction that no benefit whatever arises from it to either sex. We believe that it causes an increase of vice in the male sex, by leading men to suppose that the risk of incurring infection is, at least, very much lessened; that their moral feelings, particularly those of the young, are perverted by finding that the State undertakes to provide them with healthy prostitutes; that this engenders in the rising generation of young men a feeling of cynical brutality in their view of the mutual sexual relations. Further, we are satisfied by the evidence laid before the Parliamentary Committee that no improvement in the health of either the army or navy has been obtained through the agency of this system, while there is shown to be an increase of disease among the women, and a greater difficulty of escaping from their wretched life, as proved by the fact that the average age of the women on the register advances year by year, showing the almost impossibility of their escaping from their mode of life when once they are put upon the register. Still, it does appear, from the legal sanction given to their wretched trade, that they obtain more emolument, and so have the means of making themselves personally more attractive. Is this an advantage for public morality? Let those members of our profession who wish to know the exact truth on this question take the trouble to read the evidence given before the Parliamentary Committee. They will find abundant proof that the Acts are an utter failure in a sanitary point of view; the navy returns, published from year to year, show that contagious diseases are even more prevalent among the crews in the protected than in the unprotected stations.

Further, let me remind the profession of the utter confusion that fell upon our foreign visitors, at the International last year, when they found such a strong medical opposition in England to their favourite system, an opposition led by such names as those of John Simon, Henry Lee, and H. A. Allbutt, the result being that neither in the section of public health nor in that of military medicine did anyone venture to propose a resolution in favour of regulation, though this had been done over and over again in the different continental meetings of the Society.

I now see by your last number that you fully concur in the views of Mr. Macnamara, but as there is no probability of the Contagious Diseases Acts being extended to London, or to any other place, during the continuance of the present Parliament, seeing the prudent advice of the Select Committee that there should be no attempt to extend the Acts in the teeth of the strong opposition of the Non-conformists—this being so, I would suggest that if those (magistrates or vestries, as may be) who are responsible for keeping order in the London streets would take a hint from this city, they would find that one inspector with a dozen intelligent constables could easily maintain order from Cheapside to the Haymarket without requiring any extraordinary powers.

I am, Sir, your obedient servant,

EWING WHITTLE, M.D., M.R.I.A.

Liverpool, Nov. 15th, 1882.

\* \* The facts are so plainly conclusive as to the social value of the Acts in repressing the vice of our streets that there is really nothing to discuss. The average age of the women has increased because, happily, the proportion of young girls in the class in protected districts is reduced. The majority of the Parliamentary Committee, after a most protracted inquiry, in which every possible objection was urged, came to the conclusion "that the Acts are necessary for the good of the community."—ED. L.

### SUPRA-CLAVICULAR PSEUDO-LIPOMA.

To the Editor of THE LANCET.

SIR,—By a singular coincidence, a leaderette in your issue of Nov. 4th throws light on a case which I saw for the first time yesterday.

My patient is a man fifty-nine years of age, and had a fall a week or two ago. Since then the neck has been very stiff, and it was on account of this that he came to consult me. On examining the neck yesterday my attention immediately directed itself to a soft elastic tumour in the left supra-clavicular region. The man had been for many years in the habit of carrying sacks of corn on that shoulder, and I was at first inclined to regard it as an artificial bursa. It was, however, somewhat firm for that, and I fancied, as did also Mr. Banatvala, who saw the case with me, that I could detect some indefinite lobulation. On baring the neck completely we found a similar, but less marked, tumour on the right side, which at once disposed of the theory of the bursa, as my patient had not been in the habit of carrying on that shoulder. The tumour, however, scarcely answered fully to the description of an ordinary lipoma; and in this state of mental uncertainty I read your leaderette this morning. I have since then examined the case further, and desire to report the following facts:—The patient is of a distinctly rheumatic diathesis, having suffered from rheumatic pains in the limbs and joints for upwards of thirty years, but he has not had either acute rheumatism or rheumatic iritis. He has frequently had lumbago, and there is evidence of chronic rheumatic arthritis in the metacarpophalangeal articulations, and in the right knee-joint, besides considerable thickening and irregularity of both tibiae. The right first metacarpophalangeal articulation gives distinct crepitus on motion. The tumour itself on the left side lies in the triangular space formed by the sterno-mastoid, trapezius, and clavicle. It is two inches in diameter from the centre of the clavicle to the upper part of the tumour at the apex of the triangle, and two inches and a half from the front lower angle of the tumour, overlying the posterior border of the sterno-mastoid to the posterior upper part of the tumour in front of the anterior border of the trapezius. The skin moves freely over it, and is not discoloured. The tumour on the right side is similar to, but smaller than, that on the left. To the left of the spinous processes of the upper cervical vertebrae there is a marked, firm, and rather tender swelling, contrasting strongly with the flaccid condition of the muscles on the right of the same spines. This I take to be a hypertrophy of the trapezius, due to the patient carrying weights on the left shoulder, and possibly aggravated at the present time by slight muscular rheumatism. There is some oedema of both legs; but there are no similar swellings, either oedematous or lipomatous, in any other of the situations mentioned in your article. The urine has always been from time to time liable to deposit lithates; its specific gravity

016, but it is pale, limpid, and colourless, markedly without either albumen or sugar, and does not present appreciable quantity of uric acid. It appears to me that, *à propos* of your article, this case is of interest, and I therefore send you details to publish if you think fit.

I am, Sir, yours faithfully,  
KENNETH W. MILLICAN, B.A. Cantab., M.R.C.S.  
Inston, Warwick, Nov. 4th, 1882.

## THE RECENT BANQUET TO THE MEDICAL OFFICERS FROM EGYPT.

To the Editor of THE LANCET.

SIR,—You will greatly oblige me by kindly inserting this in your next issue to prevent any misunderstanding in what I meant to say about my Division at the banquet given by the profession to the medical officers of the Egyptian Expedition. It should have run thus:—"The death-rate (from cholera) was *nil* from August 21st to October 16th. We had an admirable ambulance corps, of which we were able to send 400 to the Army Medical Department to carry off the wounded at the battle of Tel-el-Kebir, and they did their work admirably. We gave them also an ambulance column of ninety-six dandies (stretchers), which, however, did not arrive in time for the battle, &c."

I remain, Sir, yours faithfully,  
COLVIN SMITH, M.D.,  
Deputy Surgeon-General Madras Army, lately P.M.O.,  
Indian Division, Egyptian Expedition.  
Marloes-road, Kensington, Nov. 28th, 1882.

## NEWCASTLE-ON-TYNE.

(From our own Correspondent.)

AT Sunderland the high death-rate—viz., 47.7 per 1000 by the latest returns—now prevailing is producing some anxiety in the minds of the authorities. It is, no doubt, principally owing to a very severe epidemic of measles, which is causing a mortality of about twelve children weekly. Scarlet fever is slightly in excess, and there is also typhus existing to a considerable degree. The authorities are fully alive to the matter, and are doing what they can to prevent the spread of the disease. There is another matter which may make the Sunderland death-rate appear higher than it really is, and that is that the population is believed to be in excess of the Registrar-General's estimate, for when the census was taken there were about 1453 houses uninhabited, whereas, owing to trade revival, there are now only 150 unoccupied. The occupied houses are also more crowded from the increase in employment, and more than three hundred new houses have been built, so that the population of the borough is now believed to be 130,143 at least. The death-rate from measles for a considerable time has been 5.0 per 1000 inhabitants. The typhus fever has not assumed an epidemic form, it has been principally among the Irish population, and occurring in tenemented houses; the same remark applies to small-pox, and prompt measures having been taken as to isolation and disinfection there has been no death so far from it. Much good has followed the free distribution of handbills and placards instructing the poor as to disinfection and isolation of zymotic diseases. South Shields, considering the communication constantly going on between it and Newcastle and Sunderland, would appear, as has been frequently noticed before, to enjoy some degree of immunity from epidemics; the mortality from autumn diarrhoea, which was somewhat high, has now disappeared. There is some prevalence of scarlet fever, but it has been hitherto of a mild type, and unaccompanied by any serious fatality.

The last returns of zymotic diseases notified by practitioners in Newcastle show, during the fortnight ending Nov. 11th, the presence of 109 cases of infectious disease, inclusive of thirty-six cases of small-pox. As regards the last disease there is reason to fear that these numbers are not to be accepted as a complete account of the prevalence of this disorder; for I was told by a practitioner of good standing here that in a single street in Newcastle

there had been sixteen cases of small-pox, not one of which had been attended by a medical man, and were, as a matter of course, unnotified. Poor people, from prejudice, conceal the disease if at all possible, and through ignorance, for they fear medical attendance leads to compulsory removal to the hospital, followed by destruction of their bedclothes. These cases were "prescribed" for by chemists, grocers, and old women, and were, of course, mild, or concealment would have been impossible. But what about the spread of the disease?
